Operating Systems and Networks

Network Lecture 4: Link Layer (2)

Adrian Perrig Network Security Group ETH Zürich

Pending Issues

- How to read the course textbook?
- How to prepare for the exam given that there is a huge amount of material?

Where we are in the Course

- Finishing off the Link Layer!
 - Builds on the physical layer to transfer frames over connected links

Application
Transport
Network
Link
Physical

Computer Networks

3

Topics

- 1. Framing
 - Delimiting start/end of frames

2. Error detection/correction

Handling errors

Computer Networks

Topics (2)

- 3. Retransmissions
 - Handling loss
- 4. Multiple Access
 - Classic Ethernet, 802.11
- 5. Switching
 - Modern Ethernet

Computer Networks

5

Retransmissions (ARQ) (§3.3)

- Two strategies to handle errors:
- Detect errors and retransmit frame (Automatic Repeat reQuest, ARQ)
- 2. Correct errors with an error correcting code

Computer Networks

Context on Reliability

Where in the stack should we place reliability functions?

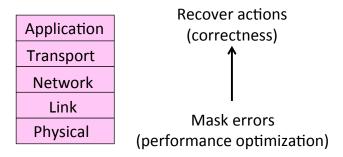

Computer Networks

7

Context on Reliability (2)

- Everywhere! It is a key issue
 - Different layers contribute differently

Computer Networks

ARQ

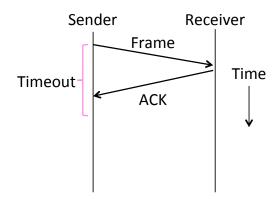

- ARQ often used when errors are common or must be corrected
 - E.g., WiFi, and TCP (later)
- Rules at sender and receiver:
 - Receiver automatically acknowledges correct frames with an ACK
 - Sender automatically resends after a timeout, until an ACK is received

Computer Networks

Ç

ARQ (2)

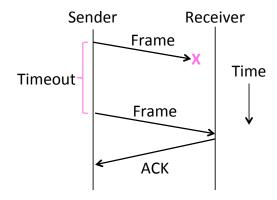

Normal operation (no loss, no error)

Computer Networks

ARQ (3)

Loss and retransmission

Computer Networks

11

So What's Tricky About ARQ?

- Two non-trivial issues:
 - How long to set the timeout?
 - How to avoid accepting duplicate frames as new frames
- Want performance in the common case and correctness always

Computer Networks

Timeouts

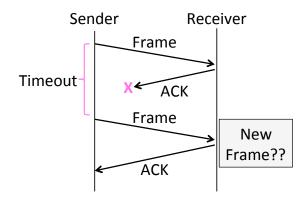

- Timeout should be:
 - Not too big (link goes idle)
 - Not too small (spurious resend)
- Fairly easy on a LAN
 - Clear worst case, little variation
- Fairly difficult over the Internet
 - Much variation, no obvious bound
 - We'll revisit this with TCP (later)

Computer Networks

13

Duplicates

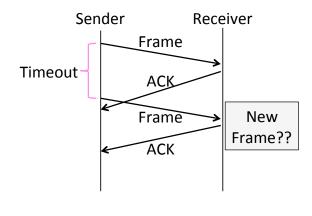

What happens if an ACK is lost?

Computer Networks

Duplicates (2)

Or the timeout is early?

Computer Networks

15

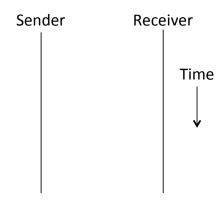

Sequence Numbers

- Frames and ACKs must both carry sequence numbers for correctness
- To distinguish the current frame from the next one, a single bit (two numbers) is sufficient
 - Called Stop-and-Wait

Computer Networks

Stop-and-Wait

In the normal case:

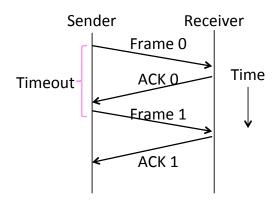

Computer Networks

17

Stop-and-Wait (2)

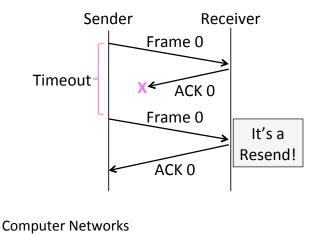

In the normal case:

Computer Networks

Stop-and-Wait (3)

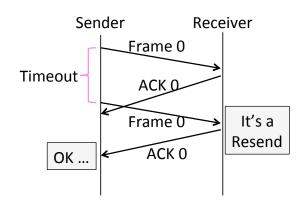

With ACK loss:

19

Stop-and-Wait (4)

With early timeout:

Computer Networks

Limitation of Stop-and-Wait

- It allows only a single frame to be outstanding from the sender:
 - Good for LAN, not efficient for high BD

- Ex: R=1 Mbps, D = 50 ms
 - How many frames/sec? If R=10 Mbps?

Computer Networks

2:

Sliding Window

- Generalization of stop-and-wait
 - Allows W frames to be outstanding
 - Can send W frames per RTT (=2D)

- Various options for numbering frames/ACKs and handling loss
 - Will look at along with TCP (later)

Computer Networks

Multiplexing (§2.5.3, 2.5.4)

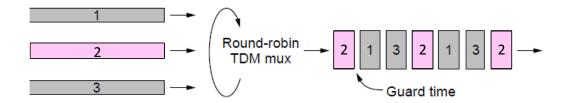

- Multiplexing is the network word for the sharing of a resource
- Classic scenario is sharing a link among different users
 - Time Division Multiplexing (TDM)
 - Frequency Division Multiplexing (FDM)

Computer Networks

2

Time Division Multiplexing (TDM)

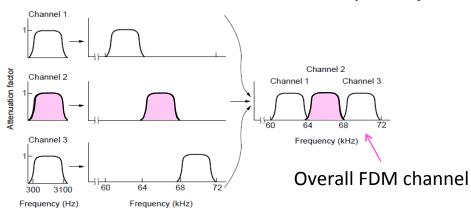

Users take turns on a fixed schedule

Computer Networks

Frequency Division Multiplexing (FDM)

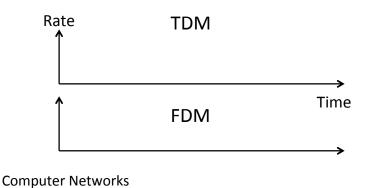

Put different users on different frequency bands

Computer Networks

TDM versus FDM

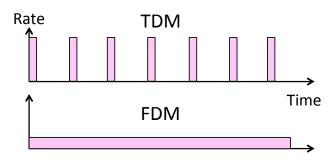

In TDM a user sends at a high rate a fraction of the time;
 in FDM, a user sends at a low rate all the time

26

TDM versus FDM (2)

In TDM a user sends at a high rate a fraction of the time;
 in FDM, a user sends at a low rate all the time

Computer Networks

27

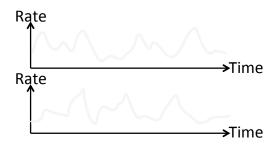

TDM/FDM Usage

- Statically divide a resource
 - Suited for continuous traffic, fixed number of users
- Widely used in telecommunications
 - TV and radio stations (FDM)
 - GSM (2G cellular) allocates calls using TDM within FDM

Computer Networks

Multiplexing Network Traffic

- Network traffic is <u>bursty</u>
 - ON/OFF sources
 - Load varies greatly over time

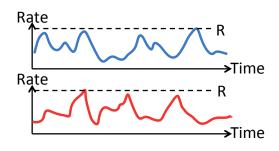

Computer Networks

29

Multiplexing Network Traffic (2)

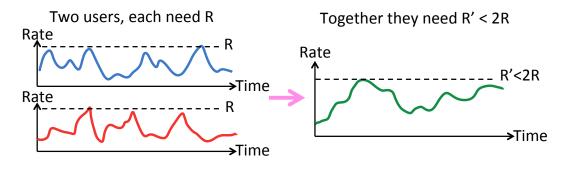

- Network traffic is <u>bursty</u>
 - Inefficient to always allocate user their ON needs with TDM/
 FDM

Computer Networks

Multiplexing Network Traffic (3)

 Multiple access schemes multiplex users according to their demands – for gains of statistical multiplexing

Computer Networks

31

Multiple Access

- We will look at two kinds of multiple access protocols
- 1. Randomized. Nodes randomize their resource access attempts
 - Good for low load situations
- 2. Contention-free. Nodes order their resource access attempts
 - Good for high load or guaranteed quality of service situations

Computer Networks

Randomized Multiple Access (§4.2.1-4.2.2, 4.3.1-4.3.3)

- How do nodes share a single link? Who sends when, e.g., in WiFI?
 - Explore with a simple model

Assume no-one is in charge; this is a distributed system

Computer Networks

33

Randomized Multiple Access (2)

- We will explore random <u>multiple access control</u> or <u>medium access control</u> (MAC) protocols
 - This is the basis for classic Ethernet
 - Remember: data traffic is bursty

Computer Networks

ALOHA Network

- Seminal computer network connecting the Hawaiian islands in the late 1960s
- , (P)
- When should nodes send?
- A new protocol was devised by Norm Abramson ...

Computer Networks

3.

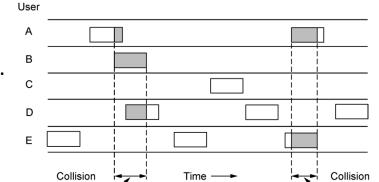

ALOHA Protocol

- Simple idea:
 - Node just sends when it has traffic.
 - If there was a collision (no ACK received) then wait a random time and resend
- That's it!

Computer Networks

ALOHA Protocol (2)

 Some frames will be lost, but many may get through...

Good idea?

Computer Networks

37

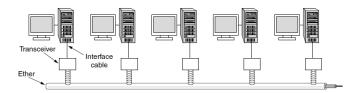

ALOHA Protocol (3)

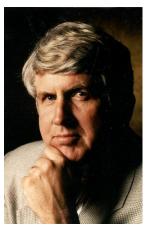

- Simple, decentralized protocol that works well under low load!
- Not efficient under high load
 - Analysis shows at most 18% efficiency
 - Improvement: divide time into slots and efficiency goes up to 36%
- We'll look at other improvements

Computer Networks

Classic Ethernet

- ALOHA inspired Bob Metcalfe to invent Ethernet for LANs in 1973
 - Nodes share 10 Mbps coaxial cable
 - Hugely popular in 1980s, 1990s

: © 2009 IEEE

Computer Networks

39

CSMA (Carrier Sense Multiple Access)

- Improve ALOHA by listening for activity before we send (Doh!)
 - Can do easily with wires, not wireless
- So does this eliminate collisions?
 - Why or why not?

Computer Networks

CSMA (2)

 Still possible to listen and hear nothing when another node is sending because of delay

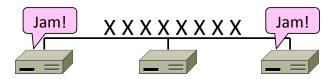

Computer Networks

41

CSMA/CD (with Collision Detection)

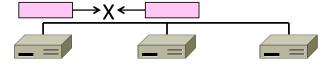

- Can reduce the cost of collisions by detecting them and aborting (Jam) the rest of the frame time
 - Again, we can do this with wires

Computer Networks

CSMA/CD Complications

- Want everyone who collides to know that it happened
 - Time window in which a node may hear of a collision is 2D seconds

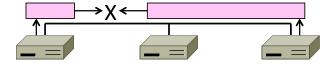

Computer Networks

43

CSMA/CD Complications (2)

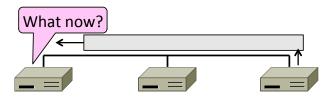

- Impose a minimum frame size that lasts for 2D seconds
 - So node can't finish before collision
 - Ethernet minimum frame is 64 bytes

Computer Networks

CSMA "Persistence"

What should a node do if another node is sending?

Idea: Wait until it is done, and send

Computer Networks

45

CSMA "Persistence" (2)

- Problem is that multiple waiting nodes will queue up then collide
 - More load, more of a problem

Computer Networks

CSMA "Persistence" (3)

- Intuition for a better solution
 - If there are N queued senders, we want each to send next with probability 1/N

Computer Networks

47

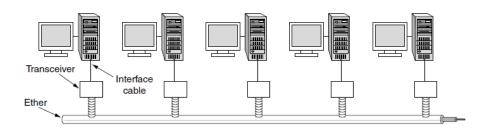

Binary Exponential Backoff (BEB)

- Cleverly estimates the probability
 - 1st collision, wait 0 or 1 frame times
 - 2nd collision, wait from 0 to 3 times
 - 3rd collision, wait from 0 to 7 times ...
- BEB doubles interval for each successive collision
 - Quickly gets large enough to work
 - Very efficient in practice

Computer Networks

Classic Ethernet, or IEEE 802.3

- Most popular LAN of the 1980s, 1990s
 - 10 Mbps over shared coaxial cable, with baseband signals
 - Multiple access with "1-persistent CSMA/CD with BEB"

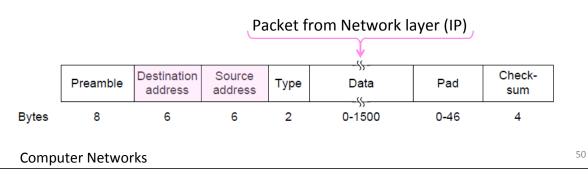

Computer Networks

49

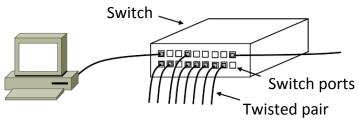

Ethernet Frame Format

- Has addresses to identify the sender and receiver
- CRC-32 for error detection; no ACKs or retransmission
- Start of frame identified with physical layer preamble

Modern Ethernet

- Based on switches, not multiple access, but still called Ethernet
 - We'll get to it later

Computer Networks

51

Wireless Multiple Access (§4.2.5, 4.4)

- How do wireless nodes share a single link? (Yes, this is WiFi!)
 - Build on our simple, wired model

Computer Networks

Wireless Complications

- Wireless is more complicated than the wired case (Surprise!)
 - Nodes may have different areas of coverage doesn't fit Carrier Sense
 - 2. Nodes can't hear while sending can't Collision Detect

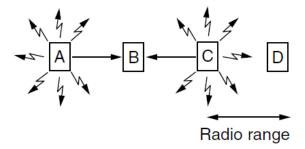

Computer Networks

53

Different Coverage Areas

 Wireless signal is broadcast and received nearby, where there is sufficient SNR

Computer Networks

Hidden Terminals

- · Nodes A and C are hidden terminals when sending to B
 - Can't hear each other (to coordinate) yet collide at B
 - We want to avoid the inefficiency of collisions

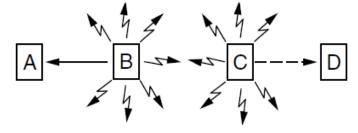

Computer Networks

5

Exposed Terminals

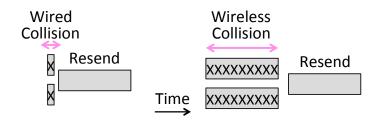

- B and C are <u>exposed terminals</u> when sending to A and D
 - Can hear each other yet don't collide at receivers A and D
 - We want to send concurrently to increase performance

Computer Networks

Nodes Can't Hear While Sending

- With wires, detecting collisions (and aborting) lowers their cost
- More wasted time with wireless

Computer Networks

57

Possible Solution: MACA

- MACA uses a short handshake instead of CSMA (Karn, 1990)
 - 802.11 uses a refinement of MACA (later)
- Protocol rules:
 - A sender node transmits a RTS (Request-To-Send, with frame length)
 - 2. The receiver replies with a CTS (Clear-To-Send, with frame length)
 - 3. Sender transmits the frame while nodes hearing the CTS stay silent
 - Collisions on the RTS/CTS are still possible, but less likely

Computer Networks

MACA - Hidden Terminals

- A→B with hidden terminal C
 - 1. A sends RTS, to B

Α

В

c

D

Computer Networks

59

MACA – Hidden Terminals (2)

- A→B with hidden terminal C
 - 2. B sends CTS, to A, and C too

A RIS B

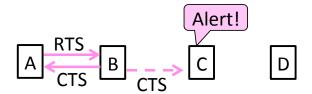

c

D

Computer Networks

MACA – Hidden Terminals (3)

- A→B with hidden terminal C
 - 2. B sends CTS, to A, and C too

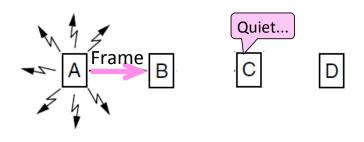

Computer Networks

61

MACA – Hidden Terminals (4)

- A→B with hidden terminal C
 - 3. A sends frame while C defers

Computer Networks

MACA – Exposed Terminals

- $B \rightarrow A$, $C \rightarrow D$ as exposed terminals
 - B and C send RTS to A and D

Α

В

| c

D

Computer Networks

63

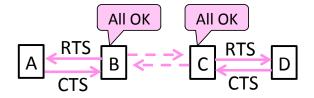

MACA – Exposed Terminals (2)

- $B \rightarrow A$, $C \rightarrow D$ as exposed terminals
 - A and D send CTS to B and C

Computer Networks

MACA – Exposed Terminals (3)

- B→A, C→D as exposed terminals
 - A and D send CTS to B and C

Computer Networks

65

MACA – Exposed Terminals (4)

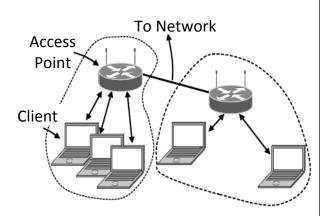

- $B \rightarrow A$, $C \rightarrow D$ as exposed terminals
 - A and D send CTS to B and C

Computer Networks

802.11, or WiFi

- Very popular wireless LAN started in the 1990s
- Clients get connectivity from a (wired) AP (Access Point)
- It's a multi-access problem ©
- Various flavors have been developed over time
 - Faster, more features

Computer Networks

67

802.11 Physical Layer

- Uses 20/40 MHz channels on ISM bands
 - 802.11b/g/n on 2.4 GHz
 - 802.11 a/n on 5 GHz
- OFDM modulation (except legacy 802.11b)
 - Different amplitudes/phases for varying SNRs
 - Rates from 6 to 54 Mbps plus error correction
 - 802.11n uses multiple antennas; see "802.11 with Multiple Antennas for Dummies"

Computer Networks

802.11 Link Layer

- Multiple access uses CSMA/CA (next); RTS/CTS optional
- Frames are ACKed and retransmitted with ARQ
- Funky addressing (three addresses!) due to AP
- Errors are detected with a 32-bit CRC
- Many, many features (e.g., encryption, power save)

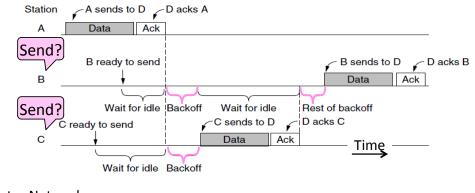

Computer Networks

69

802.11 CSMA/CA for Multiple Access

- Sender avoids collisions by inserting small random gaps
 - E.g., when both B and C send, C picks a smaller gap, goes first

Computer Networks

The Future of 802.11 (Guess)

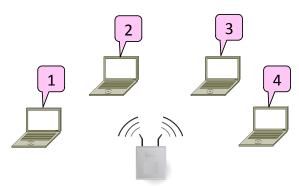

- Likely ubiquitous for Internet connectivity
 - Greater diversity, from low- to high-end devices
- Innovation in physical layer drives speed
 - And power-efficient operation too
- More seamless integration of connectivity
 - Too manual now, and limited (e.g., device-to-device)

Computer Networks

7

Contention-Free Multiple Access (§4.2.3)

- A new approach to multiple access
 - Based on turns, not randomization

Computer Networks

Issues with Random Multiple Access

- CSMA is good under low load:
 - Grants immediate access
 - Little overhead (few collisions)
- But not so good under high load:
 - High overhead (expect collisions)
 - Access time varies (lucky/unlucky)
- We want to do better under load!

Computer Networks

73

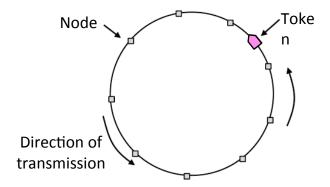

Turn-Taking Multiple Access Protocols

- They define an order in which nodes get a chance to send
 - Or pass, if no traffic at present
- We just need some ordering ...
 - E.g., Token Ring
 - E.g., node addresses

Computer Networks

Token Ring

 Arrange nodes in a ring; token rotates "permission to send" to each node in turn

Computer Networks

75

Turn-Taking Advantages

- Fixed overhead with no collisions
 - More efficient under load
- Regular chance to send with no unlucky nodes
 - Predictable service, easily extended to guaranteed quality of service

Computer Networks

Turn-Taking Disadvantages

- Complexity
 - More things that can go wrong than random access protocols!
 - E.g., what if the token is lost?
 - Higher overhead at low load

Computer Networks

77

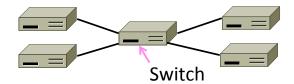

Turn-Taking in Practice

- Regularly tried as an improvement offering better service
 - E.g., qualities of service
- But random multiple access is hard to beat
 - Simple, and usually good enough
 - Scales from few to many nodes

Computer Networks

LAN Switches (§4.3.4, 4.8.1-4.8.2, 4.8.4)

- How do we connect nodes with a <u>switch</u> instead of multiple access
 - Uses multiple links/wires
 - Basis of modern (switched) Ethernet

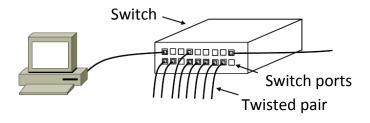

Computer Networks

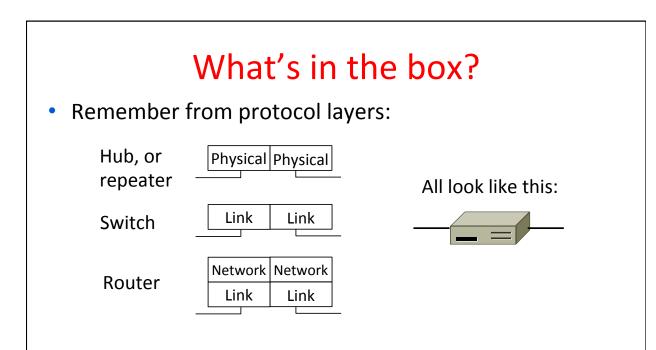

79

Switched Ethernet

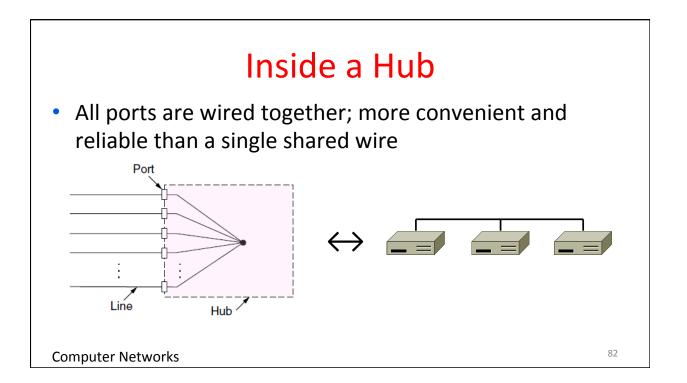

- Hosts are wired to Ethernet switches with twisted pair
 - Switch serves to connect the hosts
 - Wires usually run to a closet

Computer Networks

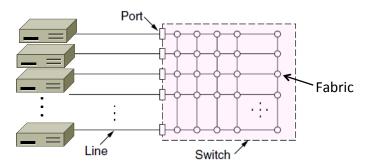

Computer Networks

Inside a Switch

 Uses frame addresses to connect input port to the right output port; multiple frames may be switched in parallel

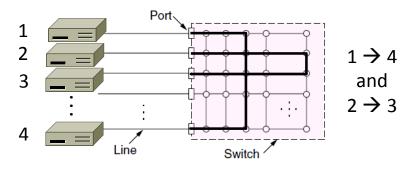

Computer Networks

83

Inside a Switch (2)

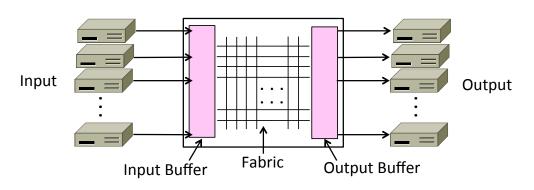

- Port may be used for both input and output (full-duplex)
 - Just send, no multiple access protocol

Computer Networks

Inside a Switch (3)

Need buffers for multiple inputs to send to one output

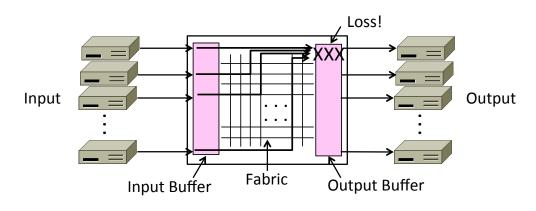

Computer Networks

85

Inside a Switch (4)

Sustained overload will fill buffer and lead to frame loss

Computer Networks

Advantages of Switches

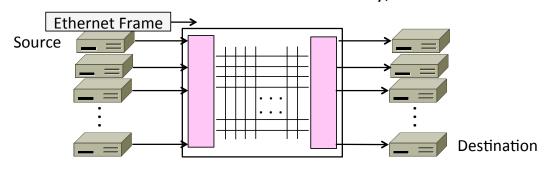

- Switches and hubs have replaced the shared cable of classic Ethernet
 - Convenient to run wires to one location
 - More reliable; wire cut is not a single point of failure that is hard to find
- Switches offer scalable performance
 - E.g., 100 Mbps per port instead of 100 Mbps for all nodes of shared cable / hub

Computer Networks

87

Switch Forwarding

- Switch needs to find the right output port for the destination address in the Ethernet frame. How?
 - Want to let hosts be moved around readily; don't look at IP

Computer Networks

Backward Learning

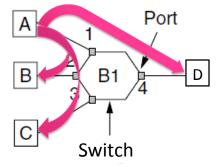

- Switch forwards frames with a port/address table as follows:
 - 1. To fill the table, it looks at the source address of input frames
 - 2. To forward, it sends to the port, or else broadcasts to all ports

Computer Networks

89

Backward Learning (2)

• 1: A sends to D

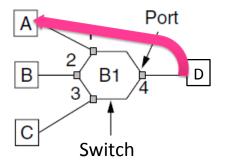

Address	Port
Α	
В	
С	
D	

Computer Networks

Backward Learning (3)

• 2: D sends to A

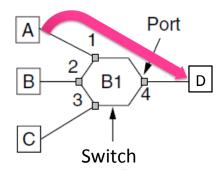

Address	Port
Α	1
В	
С	
D	

Computer Networks

91

Backward Learning (4)

• 3: A sends to D

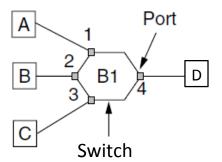

Address	Port
Α	1
В	
С	
D	4

Computer Networks

Backward Learning (5)

• 3: A sends to D

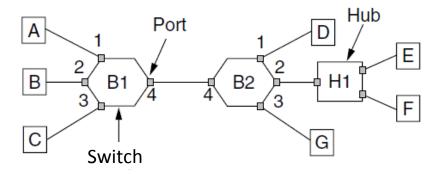

Address	Port
Α	1
В	
С	
D	4

Computer Networks

93

Learning with Multiple Switches

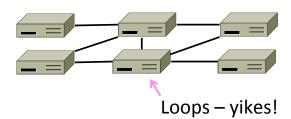

• Just works with multiple switches and a mix of hubs assuming no loops, e.g., A sends to D then D sends to A

Computer Networks

Switch Spanning Tree (§4.8.3)

- How can we connect switches in any topology so they just work
 - This is part 2 of switched Ethernet

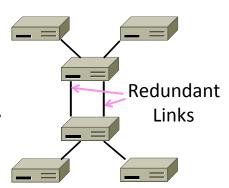

Computer Networks

95

Problem – Forwarding Loops

- May have a loop in the topology
 - Redundancy in case of failures
 - Or a simple mistake
- Want LAN switches to "just work"
 - Plug-and-play, no changes to hosts
 - But loops cause a problem ...

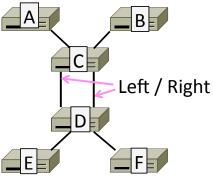

Computer Networks

Forwarding Loops (2)

Suppose the network is started and A sends to F. What

happens?

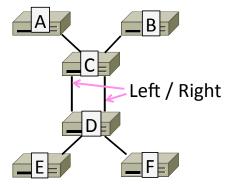

Computer Networks

97

Forwarding Loops (3)

Suppose the network is started and A sends to F. What happens?

- $-A \rightarrow C \rightarrow B$, D-left, D-right
- D-left → C-right, E, F
- D-right → C-left, E, F
- C-right → D-left, A, B
- C-left → D-right, A, B
- D-left → ...
- D-right \rightarrow ...

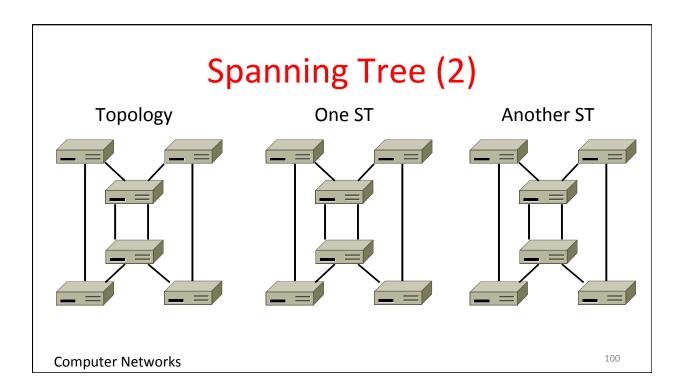

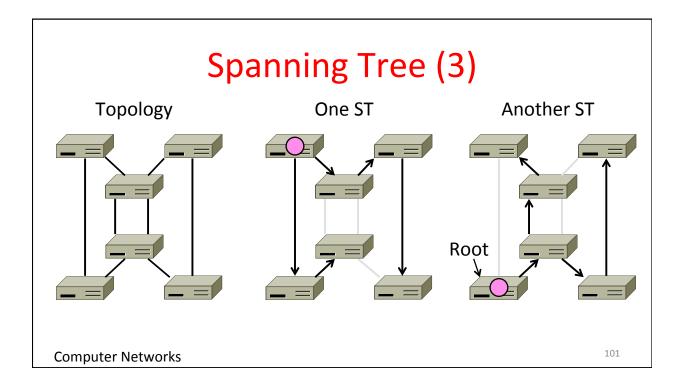

Computer Networks

Spanning Tree Solution

- Switches collectively find a <u>spanning tree</u> for the topology
 - A subset of links that is a tree (no loops) and reaches all switches
 - They switches forward as normal on the spanning tree
 - Broadcasts will go up to the root of the tree and down all the branches

Computer Networks

Spanning Tree Algorithm

- Rules of the distributed game:
 - All switches run the same algorithm
 - They start with no information
 - Operate in parallel and send messages
 - Always search for the best solution
- Ensures a highly robust solution
 - Any topology, with no configuration
 - Adapts to link/switch failures, ...

Computer Networks

Radia Perlman (1951–)

- Key early work on routing protocols
 - Routing in the ARPANET
 - Spanning Tree for switches (next)
 - Link-state routing (later)
- Now focused on network security

Computer Networks

103

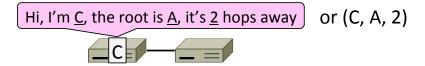

Spanning Tree Algorithm (2)

- Outline:
 - Elect a root node of the tree (switch with the lowest address)
 - 2. Grow tree as shortest distances from the root (using lowest address to break distance ties)
 - Turn off ports for forwarding if they aren't on the spanning tree

Computer Networks

Spanning Tree Algorithm (3)

- Details:
 - Each switch initially believes it is the root of the tree
 - Each switch sends periodic updates to neighbors with:
 - Its address, address of the root, and distance (in hops) to root
 - Switches favors ports with shorter distances to lowest root
 - Uses lowest address as a tie for distances

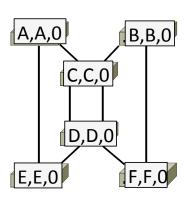

Computer Networks

105

Spanning Tree Example

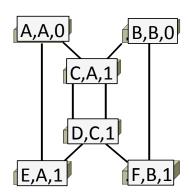

- 1st round, sending:
 - A sends (A, A, 0) to say it is root
 - B, C, D, E, and F do likewise
- 1st round, receiving:
 - A still thinks is it (A, A, 0)
 - B still thinks (B, B, 0)
 - C updates to (C, A, 1)
 - D updates to (D, C, 1)
 - E updates to (E, A, 1)
 - F updates to (F, B, 1)

Computer Networks

Spanning Tree Example (2)

- 2nd round, sending
 - Nodes send their updated state
- 2nd round receiving:
 - A remains (A, A, 0)
 - B updates to (B, A, 2) via C
 - C remains (C, A, 1)
 - D updates to (D, A, 2) via C
 - E remains (E, A, 1)
 - F remains (F, B, 1)

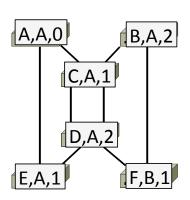

Computer Networks

107

Spanning Tree Example (3)

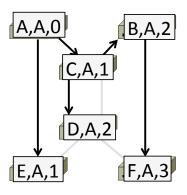

- 3rd round, sending
 - Nodes send their updated state
- 3rd round receiving:
 - A remains (A, A, 0)
 - B remains (B, A, 2) via C
 - C remains (C, A, 1)
 - D remains (D, A, 2) via C-left
 - E remains (E, A, 1)
 - F updates to (F, A, 3) via B

Computer Networks

Spanning Tree Example (4)

- 4th round
 - Steady-state has been reached
 - Nodes turn off forwarding that is not on the spanning tree
- Algorithm continues to run
 - Adapts by timing out information
 - E.g., if A fails, other nodes forget it, and B will become the new root

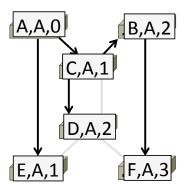

Computer Networks

100

Spanning Tree Example (5)

- Forwarding proceeds as usual on the ST
- Initially D sends to F:

• And F sends back to D:

Computer Networks

Spanning Tree Example (6)

- Forwarding proceeds as usual on the ST
- Initially D sends to F:
 - D \rightarrow C-left
 - $-C \rightarrow A, B$
 - $-A \rightarrow E$
 - $-B \rightarrow F$
- And F sends back to D:
 - $F \rightarrow B$
 - $-B \rightarrow C$
 - $c \rightarrow D$

(hm, not such a great route)

A,A,0 B,A,2 C,A,1 D,A,2 F,A,3

111

Computer Networks
