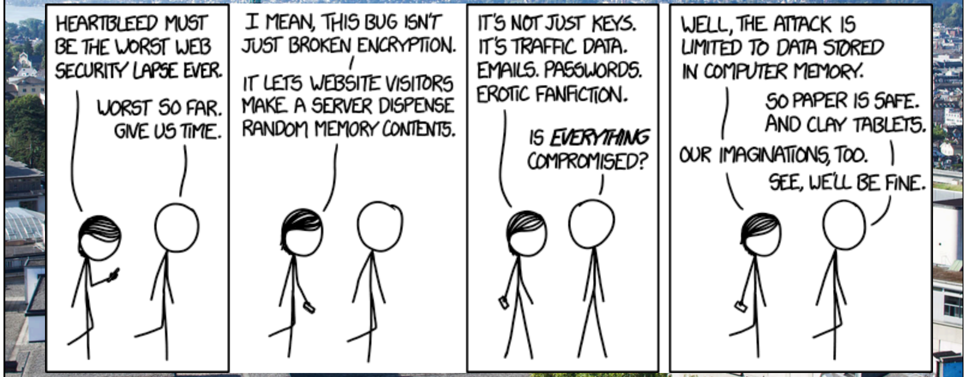
ADRIAN PERRIG & TORSTEN HOEFLER

Networks and Operating Systems (252-0062-00)
Chapter 8: Filesystem Implementation



HEARTBLEED MUST BE THE WORST WEB SECURITY LAPSE EVER.
WORST SO FAR. GIVE US TIME.
I MEAN, THIS BUG ISN'T JUST BROKEN ENCRYPTION.
IT LETS WEBSITE VISITORS MAKE A SERVER DISPENSE RANDOM MEMORY CONTENTS.
IT'S NOT JUST KEYS. IT'S TRAFFIC DATA. EMAILS. PASSWORDS. EROTIC FANFICTION.
IS EVERYTHING COMPROMISED?
WELL, THE ATTACK IS LIMITED TO DATA STORED IN COMPUTER MEMORY.
SO PAPER IS SAFE. AND CLAY TABLETS.
OUR IMAGINATIONS, TOO.
SEE, WE'LL BE FINE.

Thanks for the feedback! ☺

- **Some answers:**
  - I'll provide references to books (I'm not **only** teaching from books)
    Yesterday: "Operating Systems - An Advanced Course", Chapter 3a
    Today: Anderson/Dahlin: 11/12 (partial), 13 (full)
  - Everything that's mentioned on the slides is essential
    You should make sure you understand it
    This may require listening ☺
    Everything else and the stories I tell are optional
  - Why are your slides not self-contained?
    See Rebecca Schumann "Digital Slideshows are the scourge of education"
  - I talked to the assistants to deepen parts of the lecture in the exercise
    *I *hope* that works --- they're open for additional feedback!*
  - Next Friday is Karfreitag (probably free?)
    Exercises will not be replaced but skipped! You may go to Thursday's exercise!

File system operations

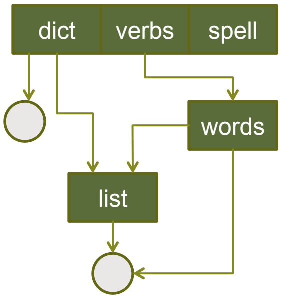
We've already seen the file system as a naming scheme.

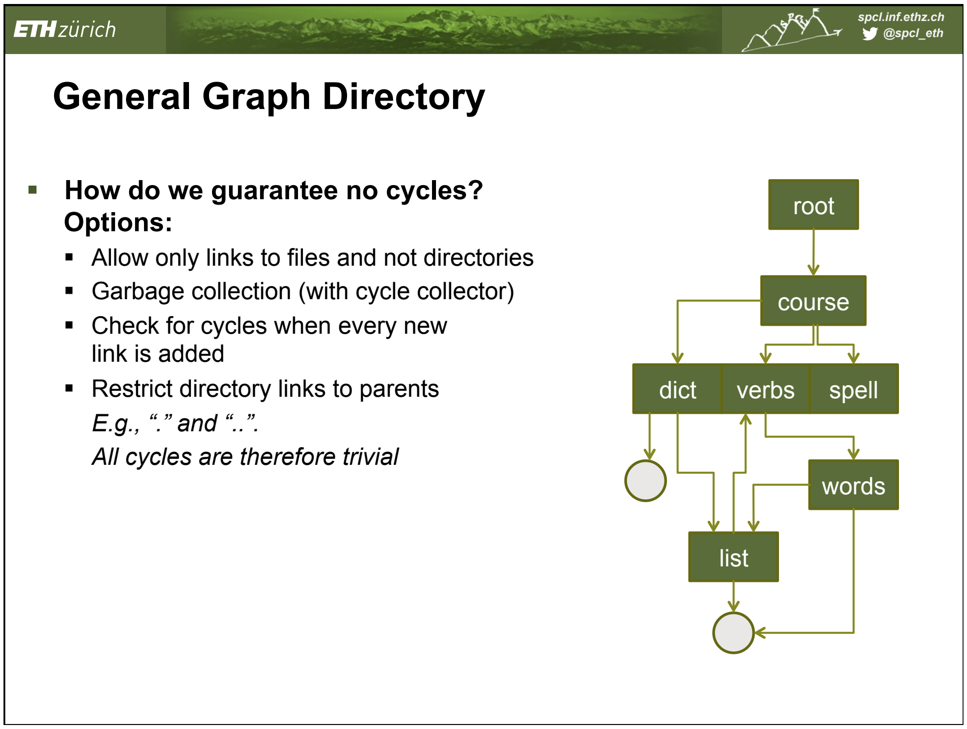
Directory (name space) operations:

- **Link (bind a name)**
- **Unlink (unbind a name)**
- **Rename**
- **List entries**

Acyclic-Graph Directories

- **Two different names (aliasing)**
- **If *dict* deletes *list* ⇒ dangling pointer**
  Solutions:
  - Backpointers, so we can delete all pointers
    Variable size records a problem
  - Backpointers using a daisy chain organization
  - Entry-hold-count solution
- **New directory entry type**
  - **Link** – another name (pointer) to an existing file
  - **Resolve the link** – follow pointer to locate the file





General Graph Directory

- **How do we guarantee no cycles? Options:**
  - Allow only links to files and not directories
  - Garbage collection (with cycle collector)
  - Check for cycles when every new link is added
  - Restrict directory links to parents
    E.g., "." and "..".
    All cycles are therefore trivial

root

course

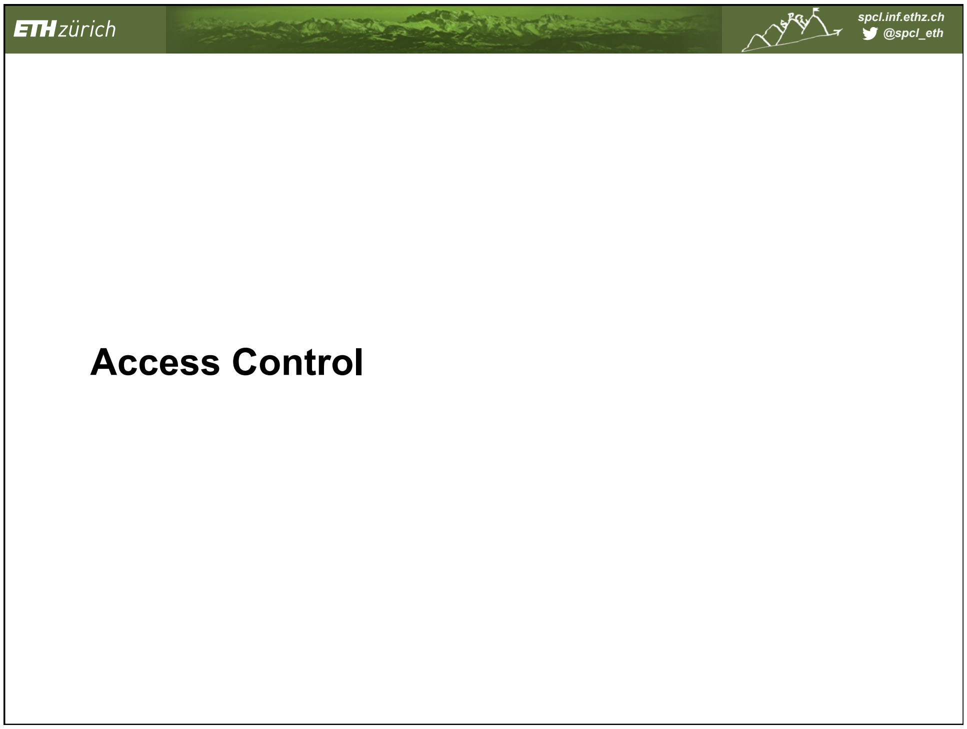
dict

verbs

spell

words

list



Access Control

Protection

- **File owner/creator should be able to control:**
  - what can be done
  - by whom

- **Types of access**
  - **Read**
  - **Write**
  - **Execute**
  - **Append**
  - **Delete**
  - **List**

Access control matrix

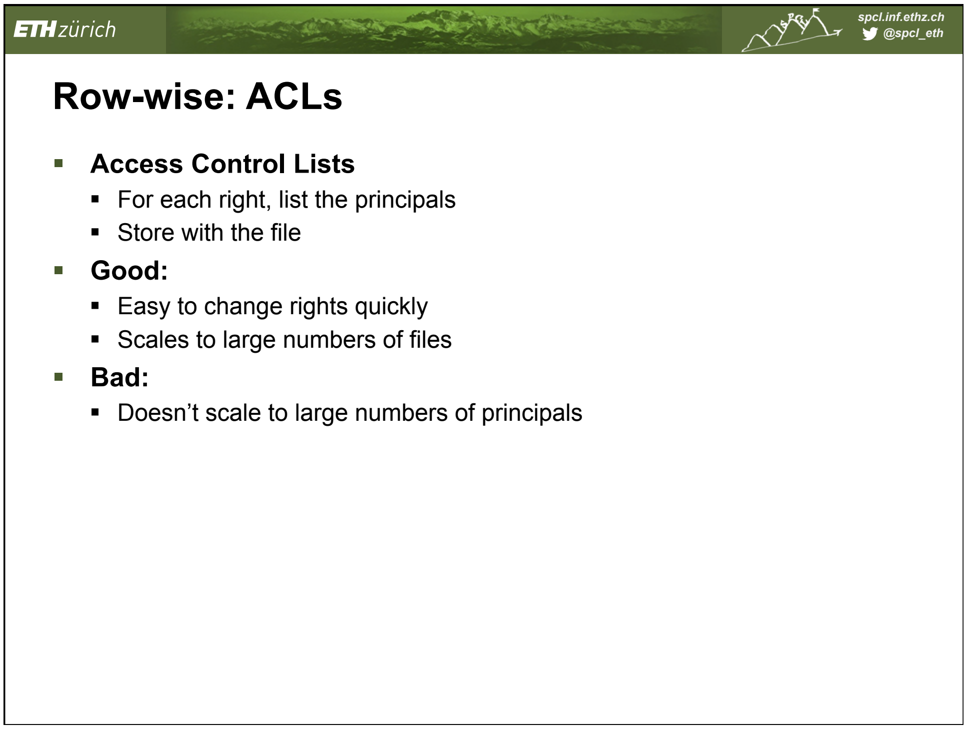
For a single file or directory:

Principals

Rights

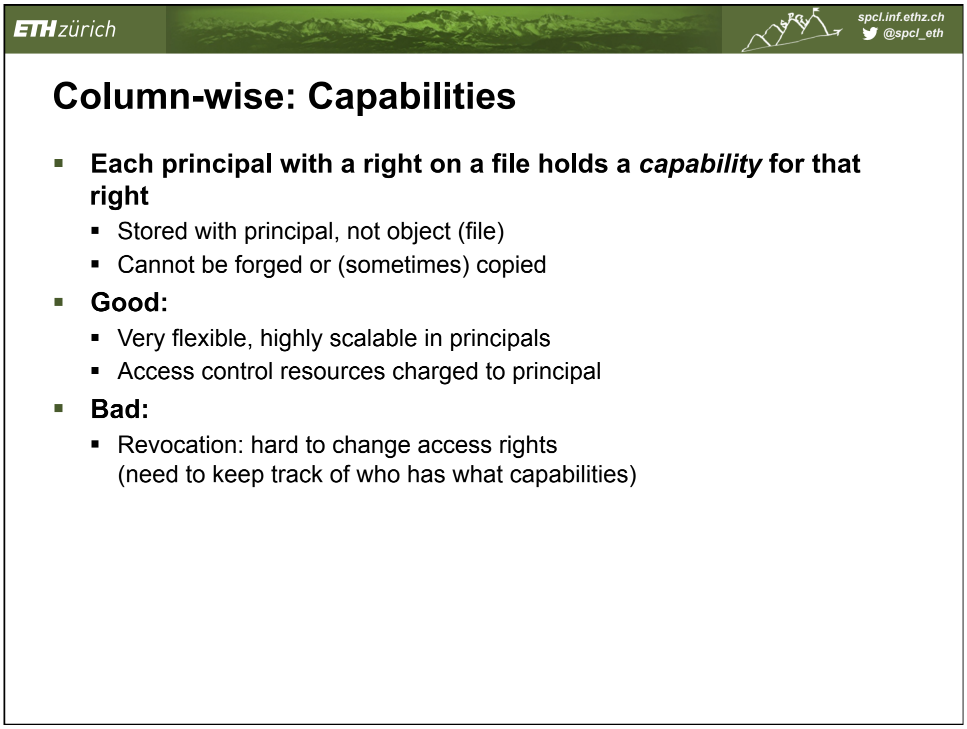
	A	B	C	D	E	F	G	H	J	…
Read	☑	☑	☑			☑	☑			
Write	☑	☑		☑			☑			
Append	☑				☑					
Execute	☑	☑	☑	☑						
Delete	☑									
List	☑				☑					
…										

Problem: how to scalably represent this matrix?



Row-wise: ACLs

- **Access Control Lists**
  - For each right, list the principals
  - Store with the file
- **Good:**
  - Easy to change rights quickly
  - Scales to large numbers of files
- **Bad:**
  - Doesn’t scale to large numbers of principals



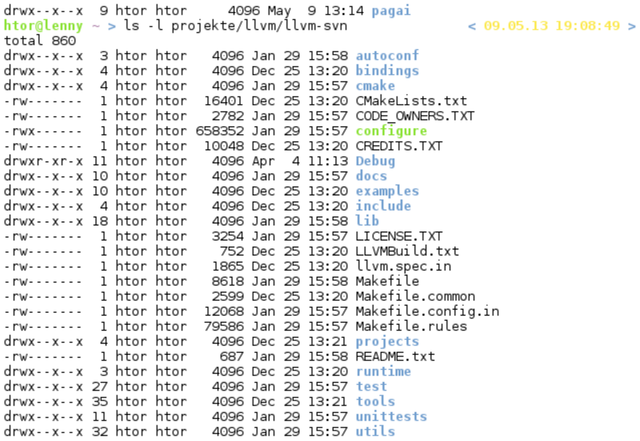
Column-wise: Capabilities

- **Each principal with a right on a file holds a *capability* for that right**
  - Stored with principal, not object (file)
  - Cannot be forged or (sometimes) copied
- **Good:**
  - Very flexible, highly scalable in principals
  - Access control resources charged to principal
- **Bad:**
  - Revocation: hard to change access rights
    (need to keep track of who has what capabilities)

POSIX (Unix) Access Control

- **Simplifies ACLs: each file identifies 3 principals:**
  - Owner (a single user)
  - Group (a collection of users, defined elsewhere)
  - The World (everyone)
- **For each principal, file defines 3 rights:**
  - Read (or traverse, if a directory)
  - Write (or create a file, if a directory)
  - Execute (or list, if a directory)

Example



```
drwx--x--x  9 htor htor     4096 May  9 13:14 pagai
htor@lenny ~ > ls -l projekte/llvm/llvm-svn                < 09.05.13 19:08:49 >

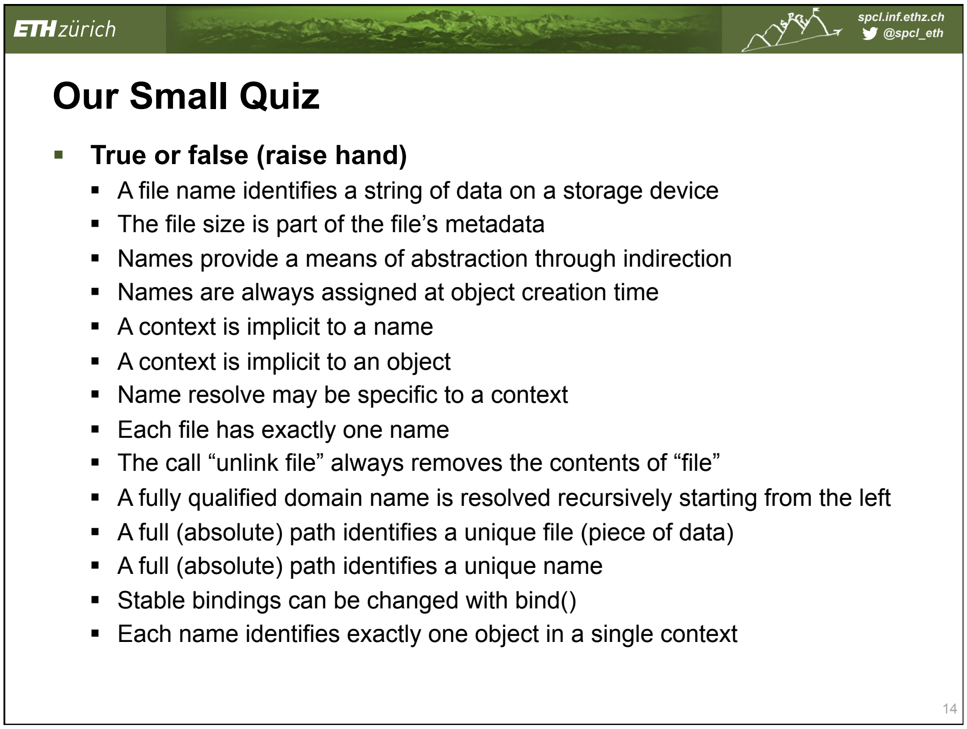
Full ACLs

- **POSIX now supports full ACLs**
  - Rarely used, interestingly
  - setfacl, getfacl, …
- **Windows has very powerful ACL support**
  - Arbitrary groups as principals
  - Modification rights
  - Delegation rights



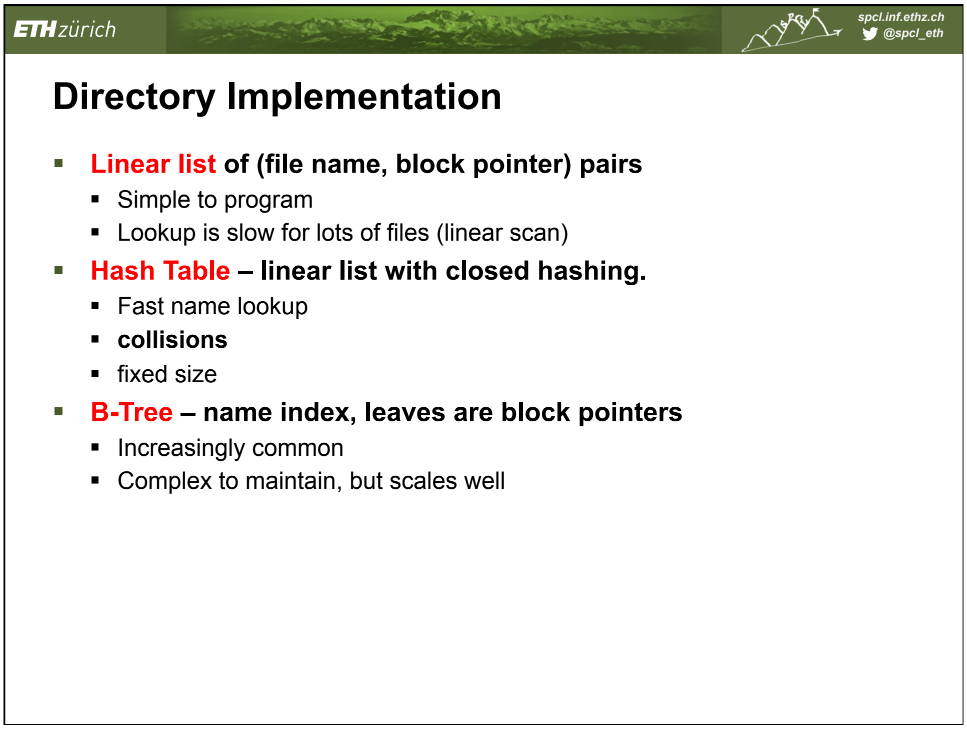
Our Small Quiz

- **True or false (raise hand)**
  - A file name identifies a string of data on a storage device
  - The file size is part of the file’s metadata
  - Names provide a means of abstraction through indirection
  - Names are always assigned at object creation time
  - A context is implicit to a name
  - A context is implicit to an object
  - Name resolve may be specific to a context
  - Each file has exactly one name
  - The call “unlink file” always removes the contents of “file”
  - A fully qualified domain name is resolved recursively starting from the left
  - A full (absolute) path identifies a unique file (piece of data)
  - A full (absolute) path identifies a unique name
  - Stable bindings can be changed with bind()
  - Each name identifies exactly one object in a single context

File types

Is a directory a file?

- **Yes…**
  - Allocated just like a file on disk
  - Has entries in other directories like a file
- **…and No…**
  - Users can't be allowed to read/write to it
    Corrupt file system data structures
    Bypass security mechanisms
  - File system provides special interface
    `opendir`, ***`closedir`***, ***`readdir`***, ***`seekdir`***, ***`telldir`***, *etc.*

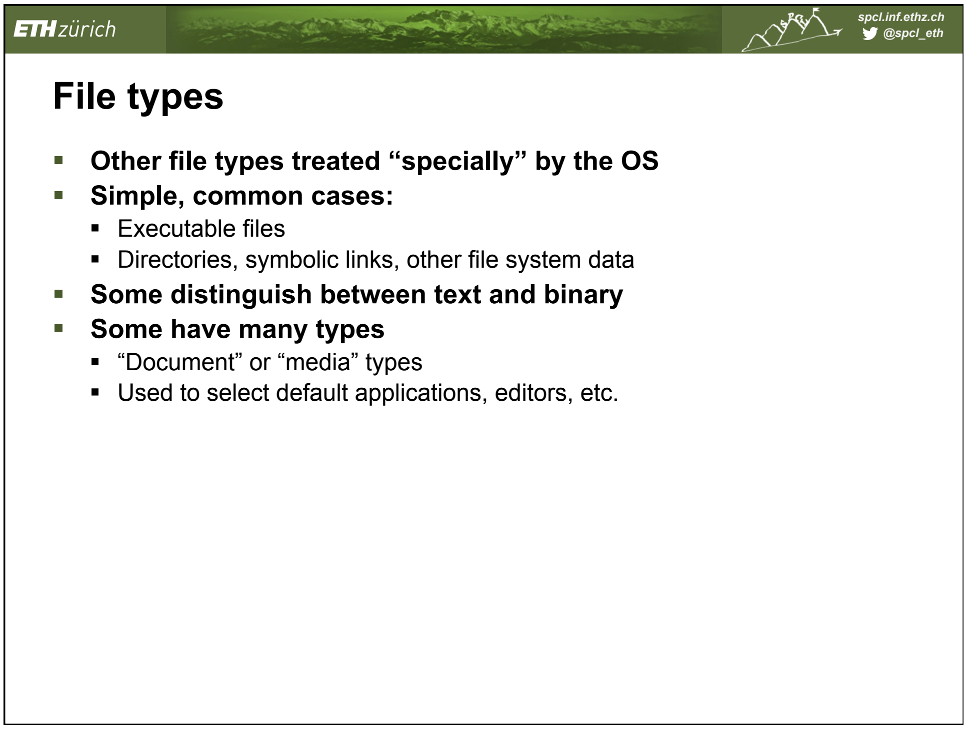


ETH zürich

spcl.inf.ethz.ch
@spcl_eth

Directory Implementation

- Linear list of (file name, block pointer) pairs
  - Simple to program
  - Lookup is slow for lots of files (linear scan)
- Hash Table – linear list with closed hashing.
  - Fast name lookup
  - **collisions**
  - fixed size
- B-Tree – name index, leaves are block pointers
  - Increasingly common
  - Complex to maintain, but scales well

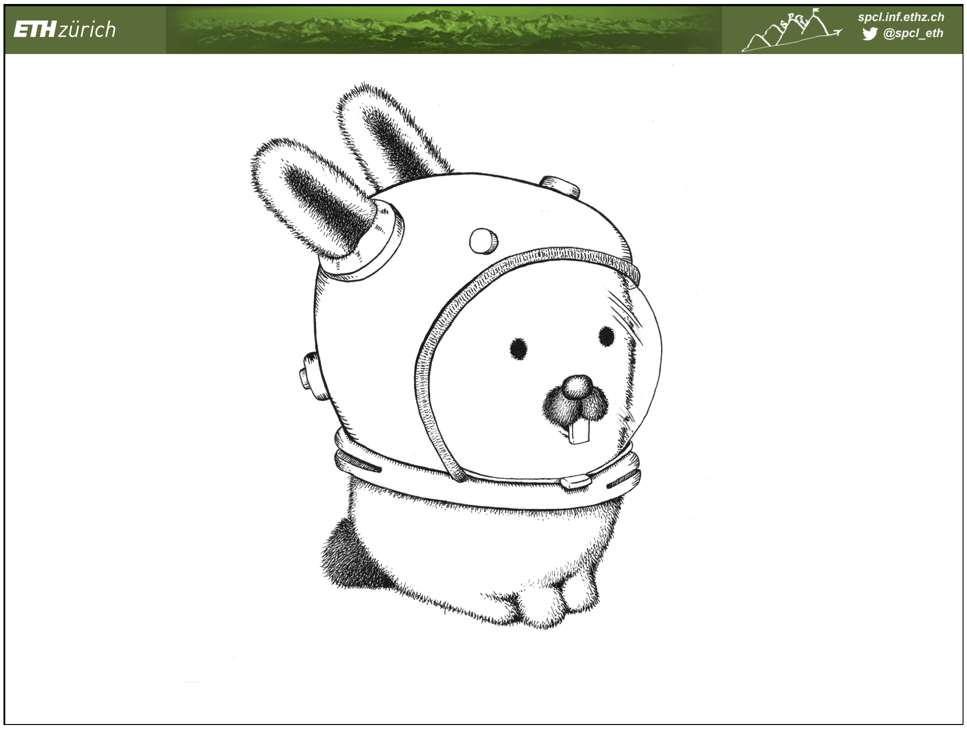


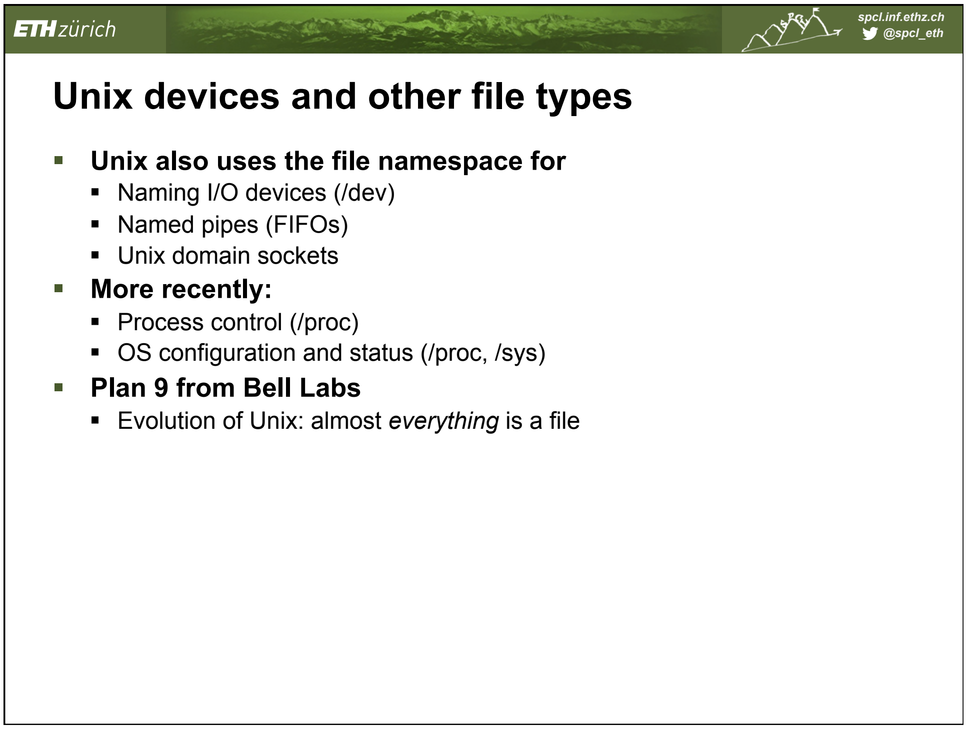
ETH zürich

spcl.inf.ethz.ch
@spcl_eth

File types

- **Other file types treated “specially” by the OS**
- **Simple, common cases:**
  - Executable files
  - Directories, symbolic links, other file system data
- **Some distinguish between text and binary**
- **Some have many types**
  - “Document” or “media” types
  - Used to select default applications, editors, etc.

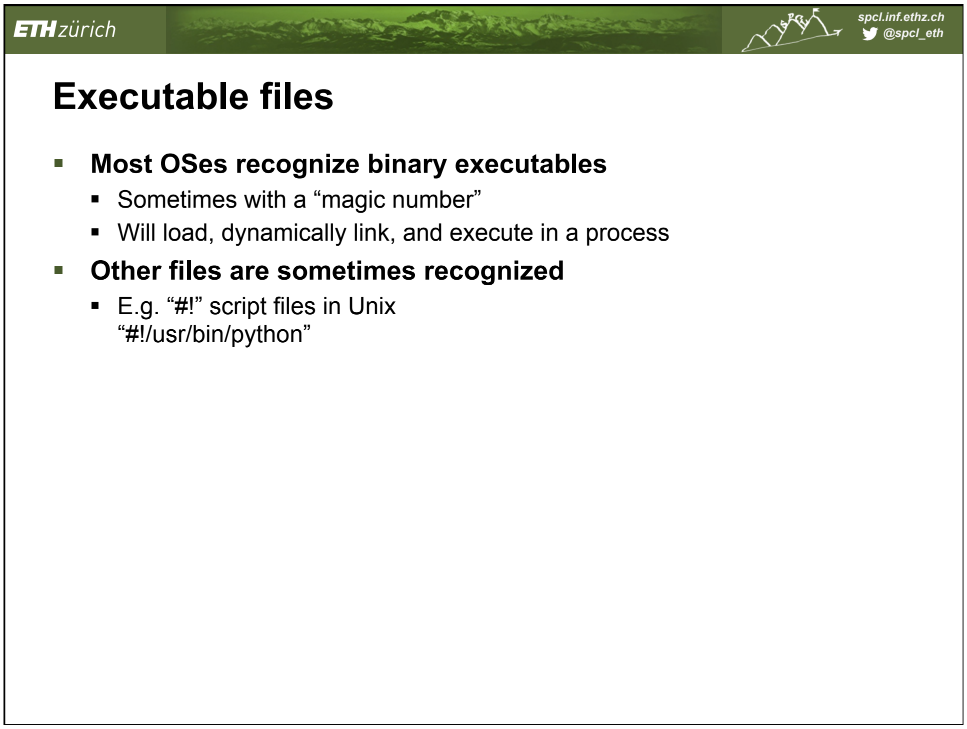




ETH zürich
spcl.inf.ethz.ch
@spcl_eth

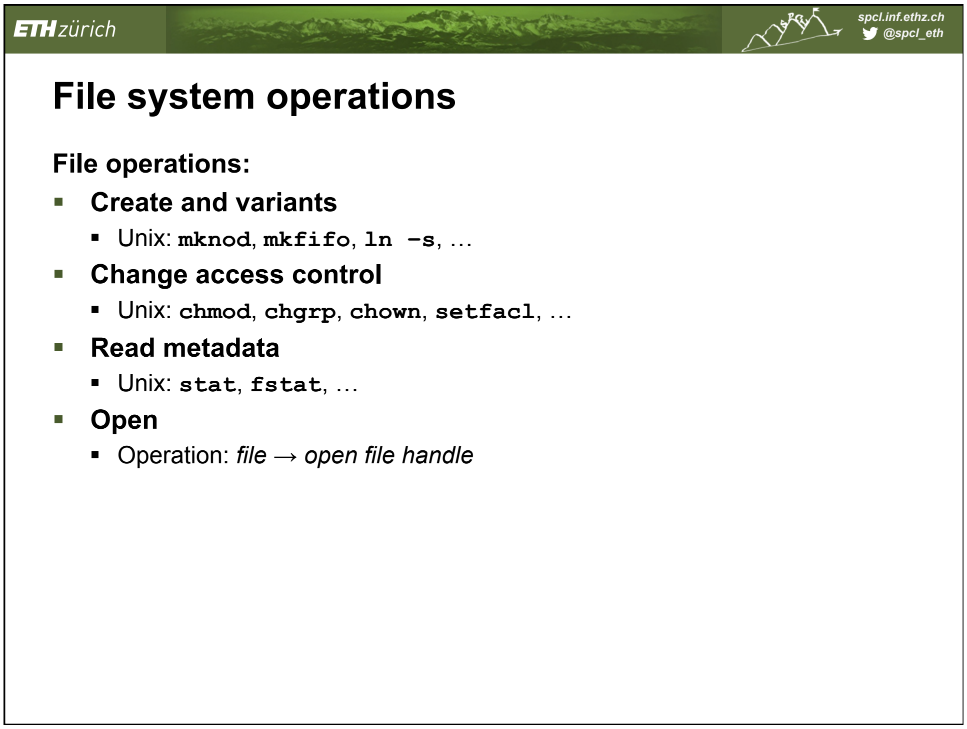
Unix devices and other file types

- **Unix also uses the file namespace for**
  - Naming I/O devices (/dev)
  - Named pipes (FIFOs)
  - Unix domain sockets
- **More recently:**
  - Process control (/proc)
  - OS configuration and status (/proc, /sys)
- **Plan 9 from Bell Labs**
  - Evolution of Unix: almost *everything* is a file



Executable files

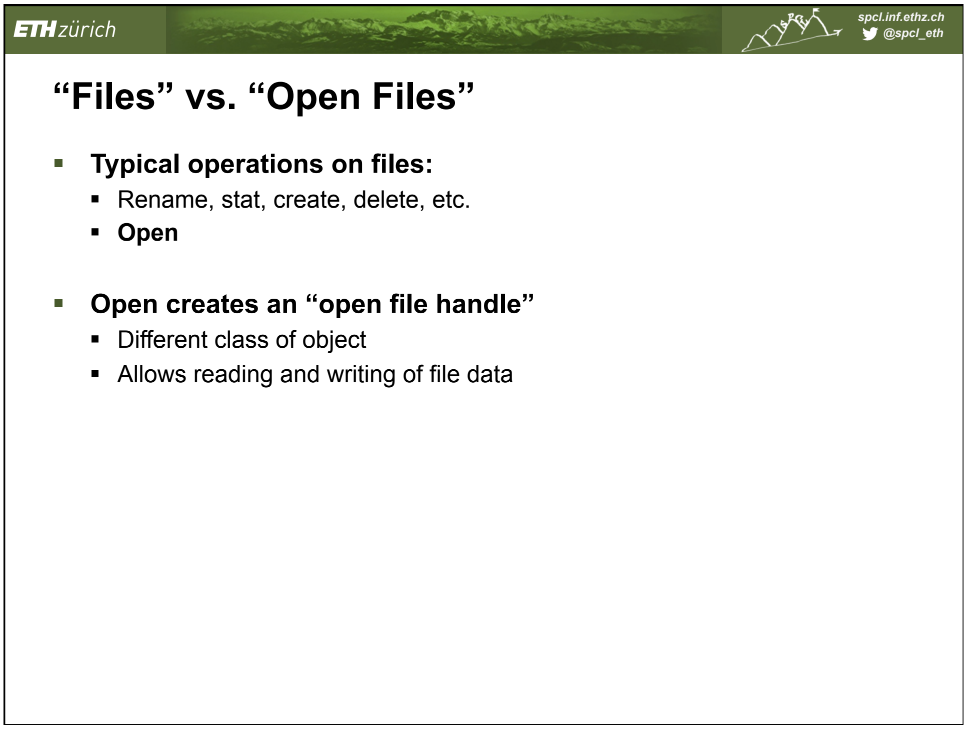
- **Most OSes recognize binary executables**
  - Sometimes with a “magic number”
  - Will load, dynamically link, and execute in a process
- **Other files are sometimes recognized**
  - E.g. “#!” script files in Unix
    “#!/usr/bin/python”



File system operations

File operations:

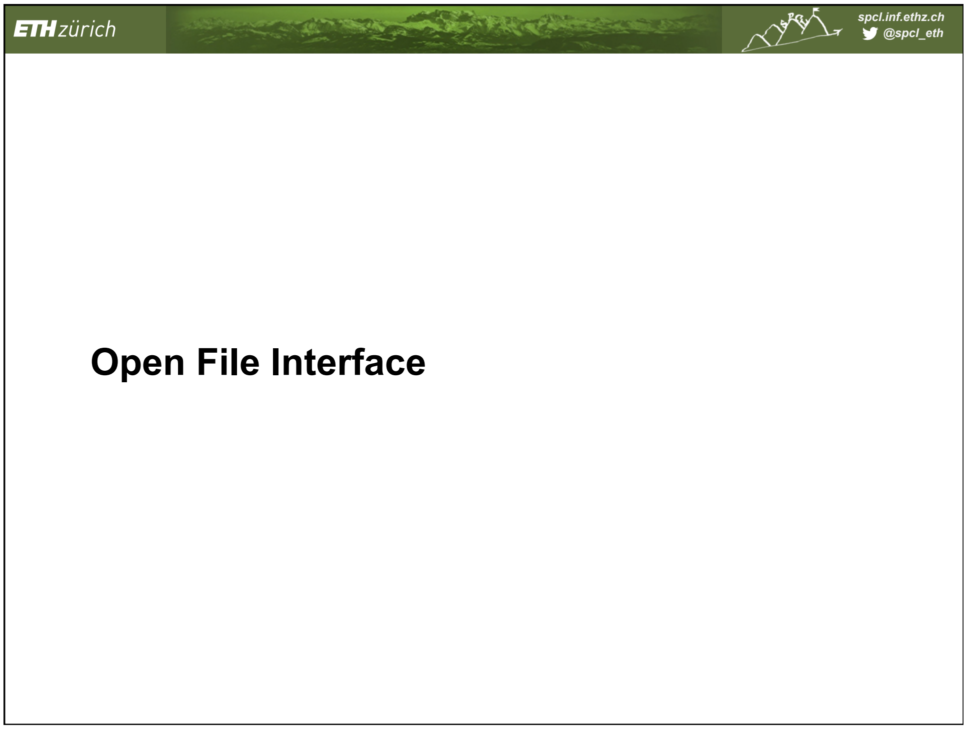
- **Create and variants**
  - Unix: `mknod`, `mkfifo`, `ln -s`, …
- **Change access control**
  - Unix: `chmod`, `chgrp`, `chown`, `setfacl`, …
- **Read metadata**
  - Unix: `stat`, `fstat`, …
- **Open**
  - Operation: *file* → *open file handle*



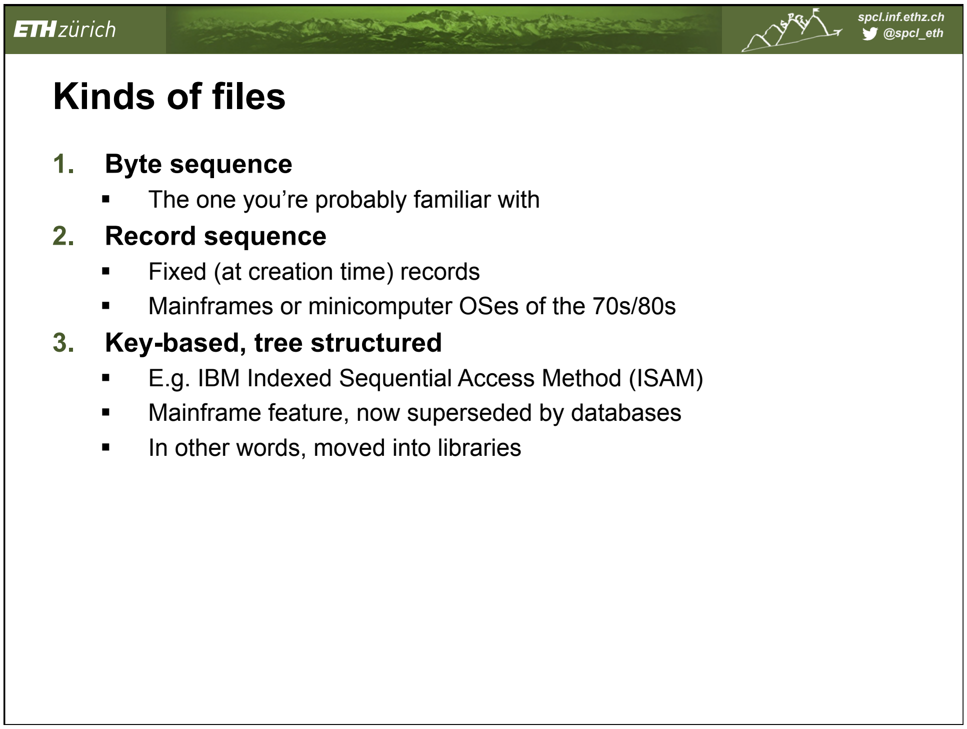
“Files” vs. “Open Files”

- **Typical operations on files:**
  - Rename, stat, create, delete, etc.
  - **Open**

- **Open creates an “open file handle”**
  - Different class of object
  - Allows reading and writing of file data

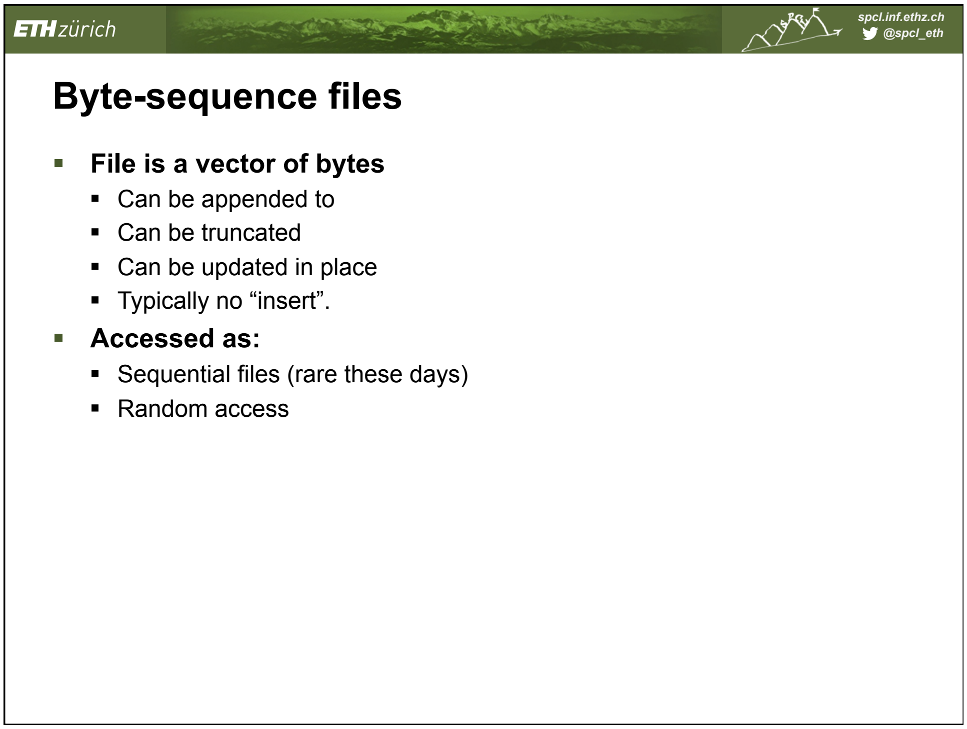


Open File Interface



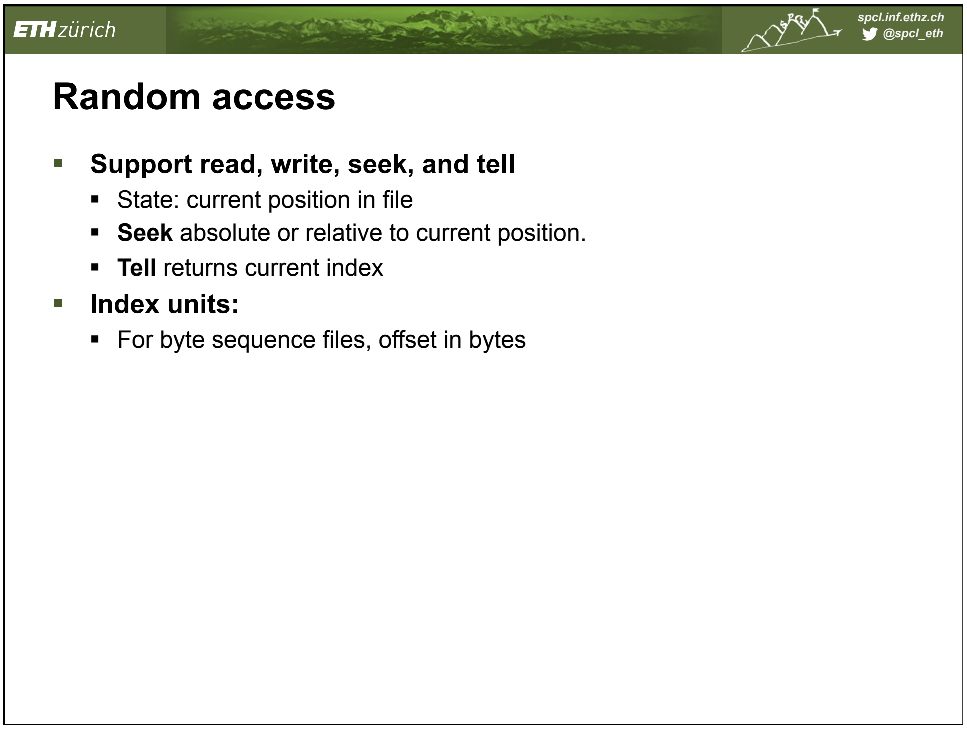
Kinds of files

1. **Byte sequence**
   - The one you're probably familiar with
2. **Record sequence**
   - Fixed (at creation time) records
   - Mainframes or minicomputer OSes of the 70s/80s
3. **Key-based, tree structured**
   - E.g. IBM Indexed Sequential Access Method (ISAM)
   - Mainframe feature, now superseded by databases
   - In other words, moved into libraries



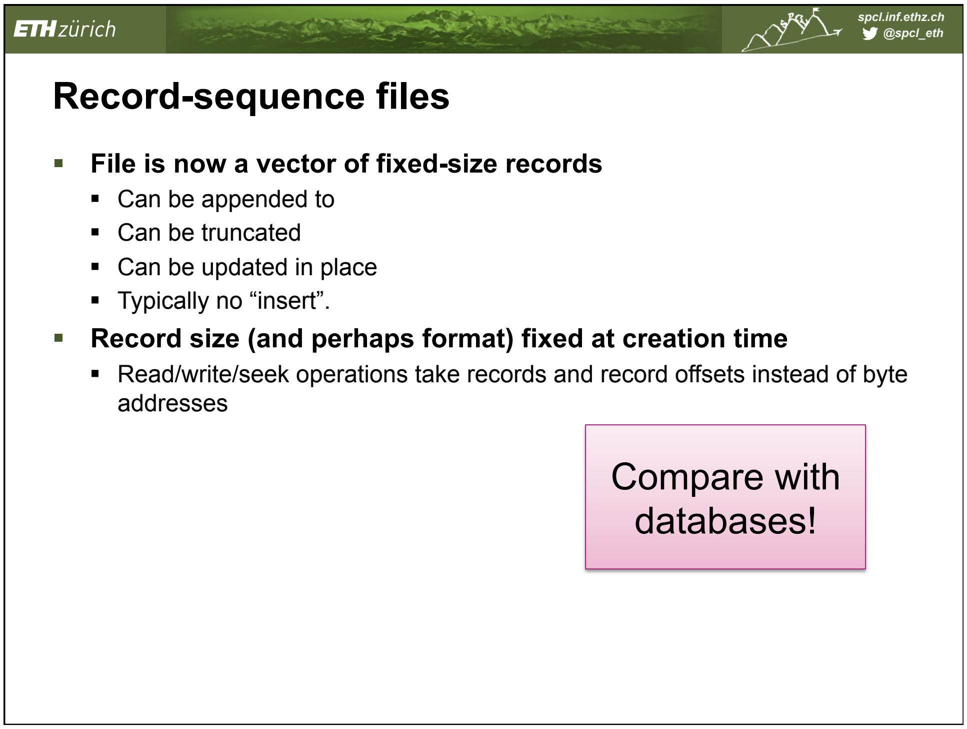
Byte-sequence files

- **File is a vector of bytes**
  - Can be appended to
  - Can be truncated
  - Can be updated in place
  - Typically no "insert".
- **Accessed as:**
  - Sequential files (rare these days)
  - Random access



Random access

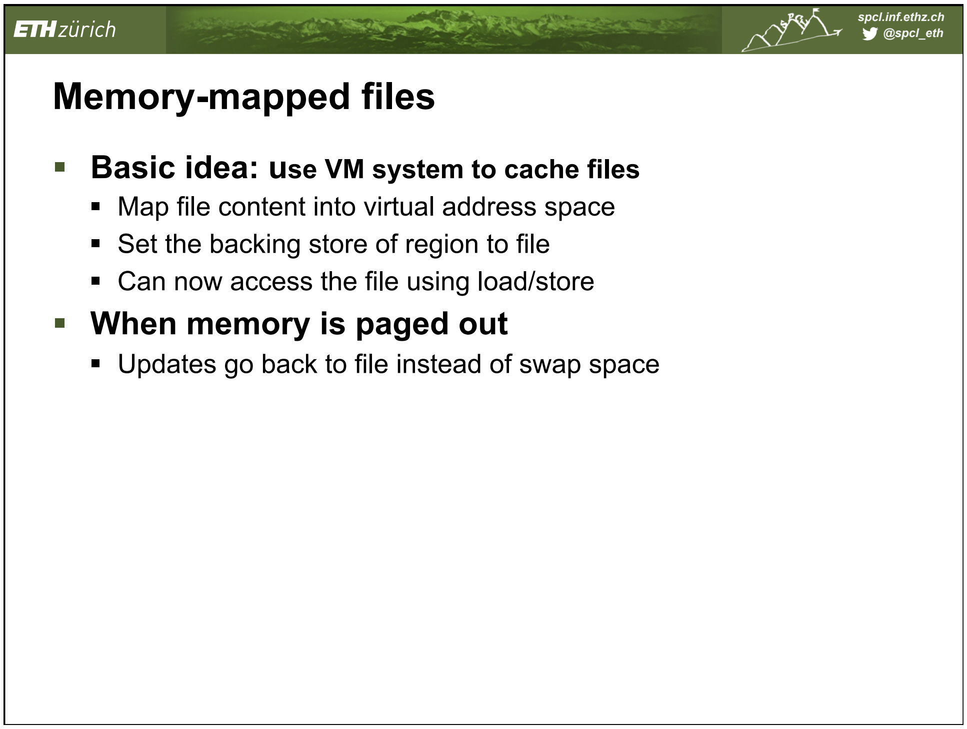
- **Support read, write, seek, and tell**
  - State: current position in file
  - **Seek** absolute or relative to current position.
  - **Tell** returns current index
- **Index units:**
  - For byte sequence files, offset in bytes



Record-sequence files

- **File is now a vector of fixed-size records**
  - Can be appended to
  - Can be truncated
  - Can be updated in place
  - Typically no “insert”.
- **Record size (and perhaps format) fixed at creation time**
  - Read/write/seek operations take records and record offsets instead of byte addresses

Compare with databases!

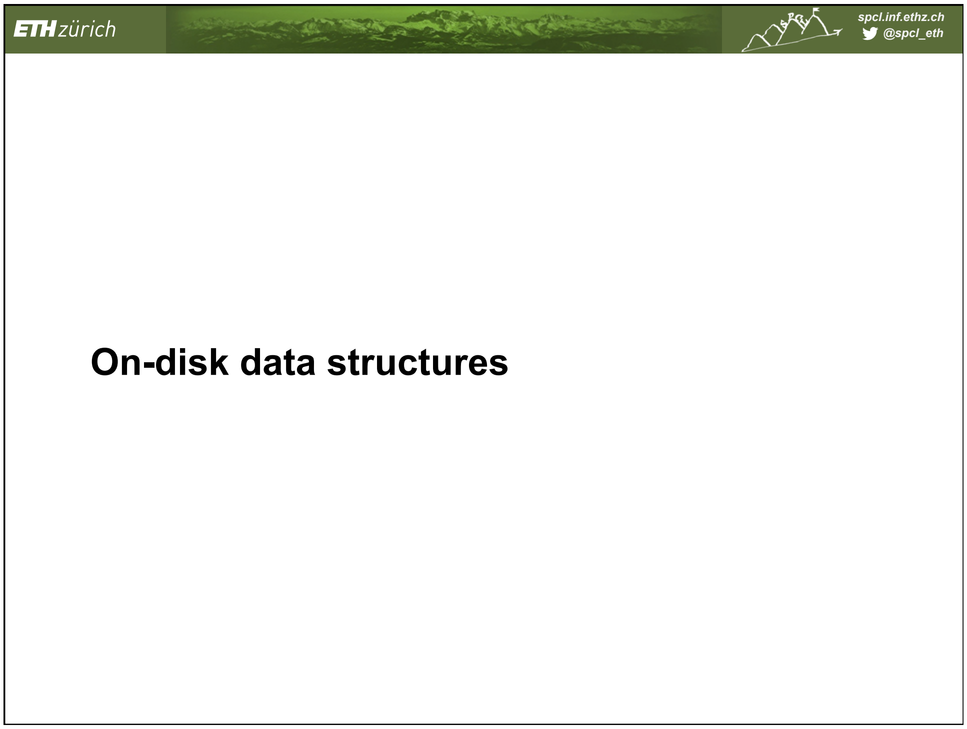


ETH zürich

spcl.inf.ethz.ch
@spcl_eth

Memory-mapped files

- **Basic idea: use VM system to cache files**
  - Map file content into virtual address space
  - Set the backing store of region to file
  - Can now access the file using load/store
- **When memory is paged out**
  - Updates go back to file instead of swap space



ETH zürich

spcl.inf.ethz.ch
@spcl_eth

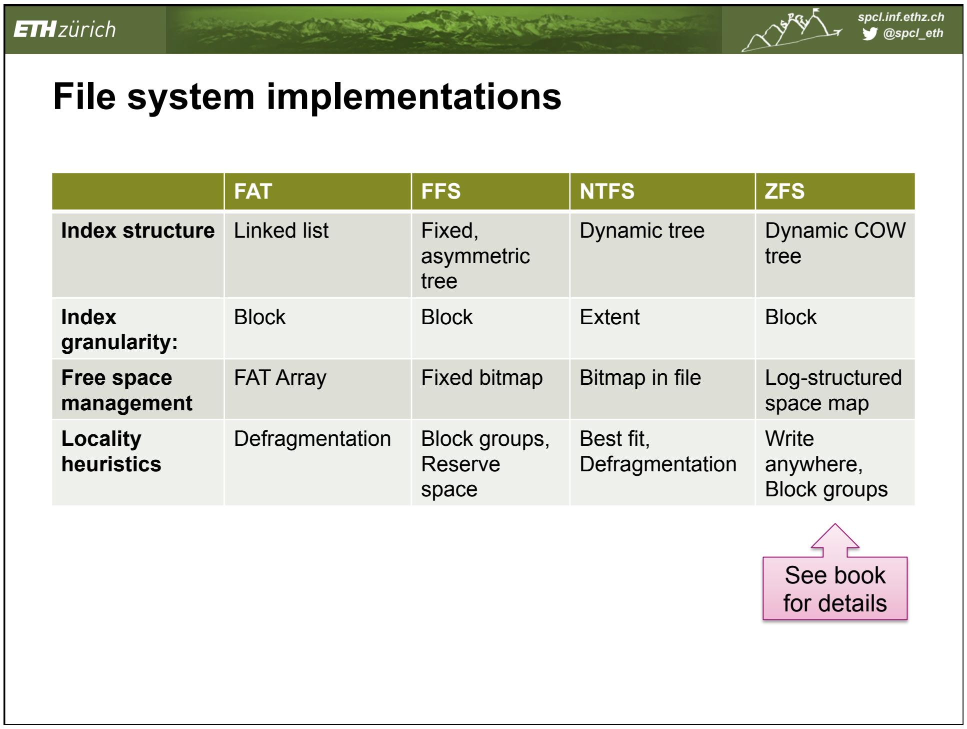
On-disk data structures

Disk addressing

- **Disks have tracks, sectors, spindles, etc.**
  - And bad sector maps!
- **More convenient to use *logical block addresses***
  - Treat disk as compact linear array of usable blocks
  - Block size typically 512 bytes
  - Ignore geometry except for performance (later!)
- **Also abstracts other block storage devices**
  - Flash drives (load-levelling, etc.)
  - Storage-area Networks (SANs)
  - Virtual disks (RAM, RAID, etc.)

Implementation aspects

- **Directories and indexes**
  - Where on the disk is the data for each file?
- **Index granularity**
  - What is the unit of allocation for files?
- **Free space maps**
  - How to allocate more sectors on the disk?
- **Locality optimizations**
  - How to make it go fast in the common case



ETH zürich

spcl.inf.ethz.ch
@spcl_eth

File system implementations

	FAT	FFS	NTFS	ZFS
Index structure	Linked list	Fixed, asymmetric tree	Dynamic tree	Dynamic COW tree
Index granularity:	Block	Block	Extent	Block
Free space management	FAT Array	Fixed bitmap	Bitmap in file	Log-structured space map
Locality heuristics	Defragmentation	Block groups, Reserve space	Best fit, Defragmentation	Write anywhere, Block groups

See book for details

FAT-32

ETH zürich

spcl.inf.ethz.ch
@spcl_eth

FAT background

- Very old – dates back to 1970s!
- No access control
- Very little metadata
- Limited volume size
- No support for hard links
- BUT still extensively used ☹
  - Flash devices, cameras, phones

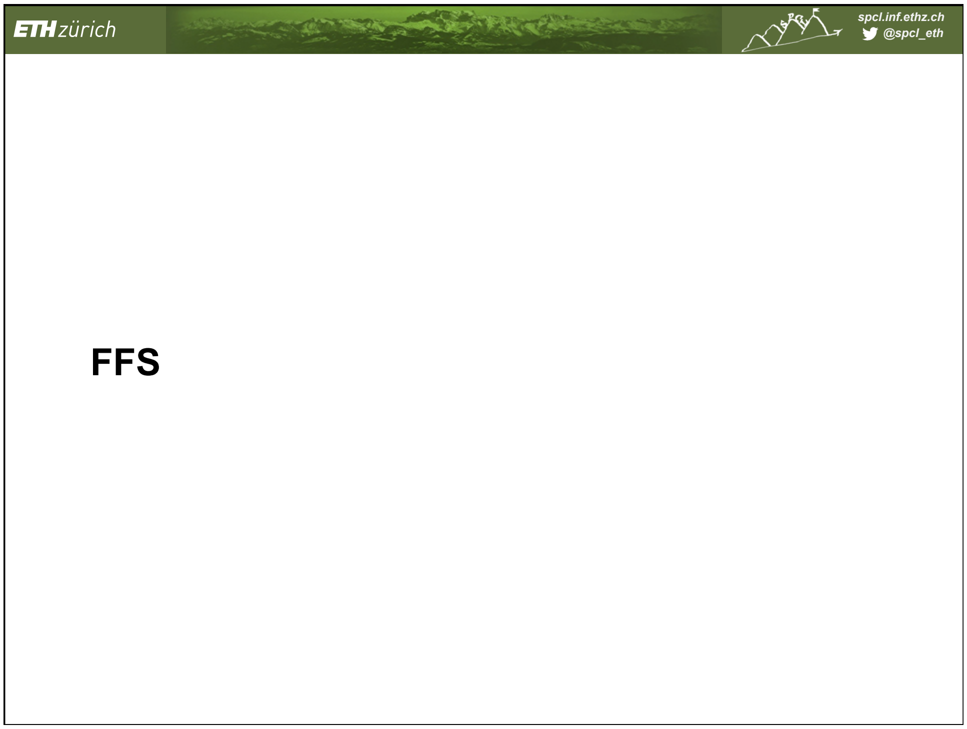
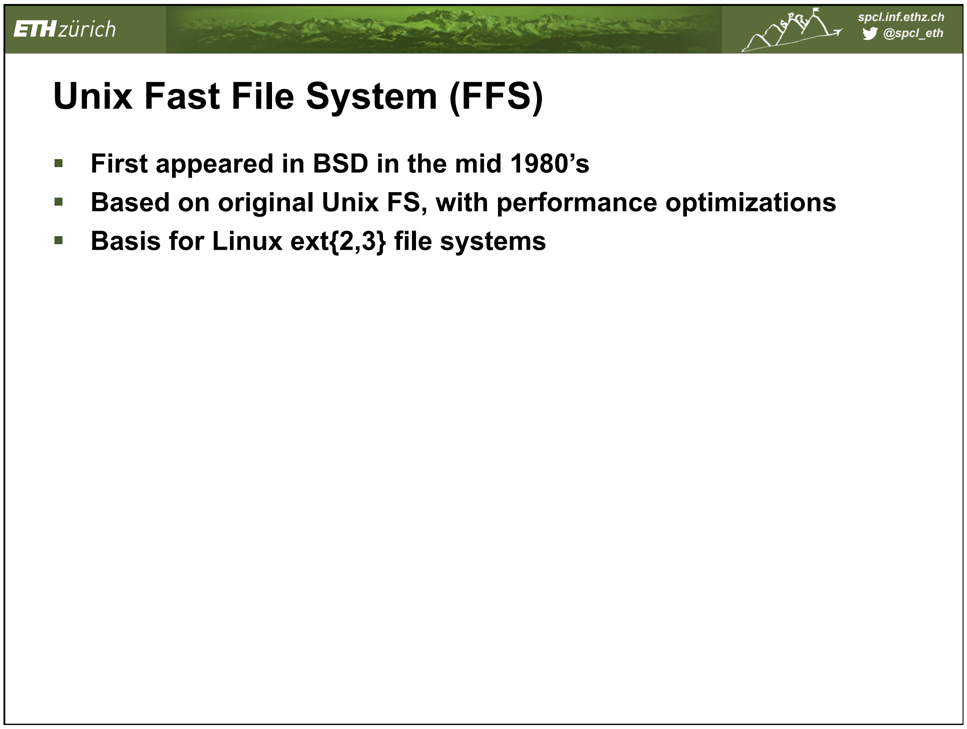
Poor locality: files can end up *fragmented* on disk



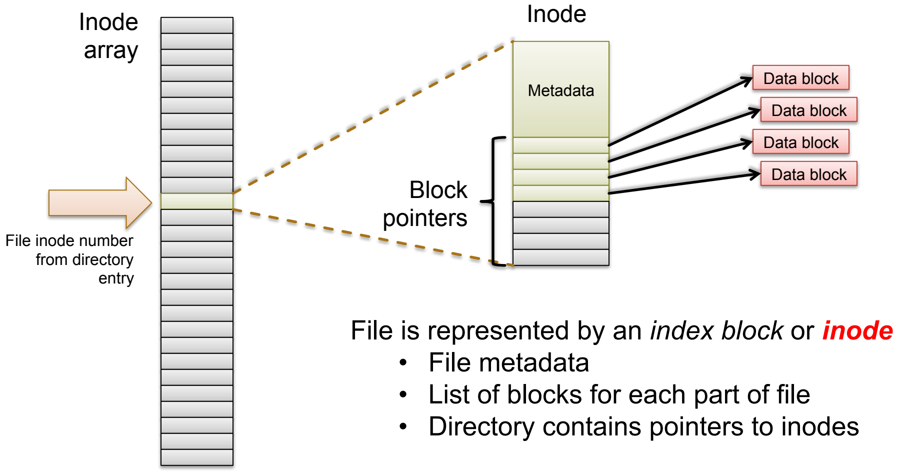
FFS



Unix Fast File System (FFS)

- First appeared in BSD in the mid 1980's
- Based on original Unix FS, with performance optimizations
- Basis for Linux ext{2,3} file systems

FFS uses indexed allocation

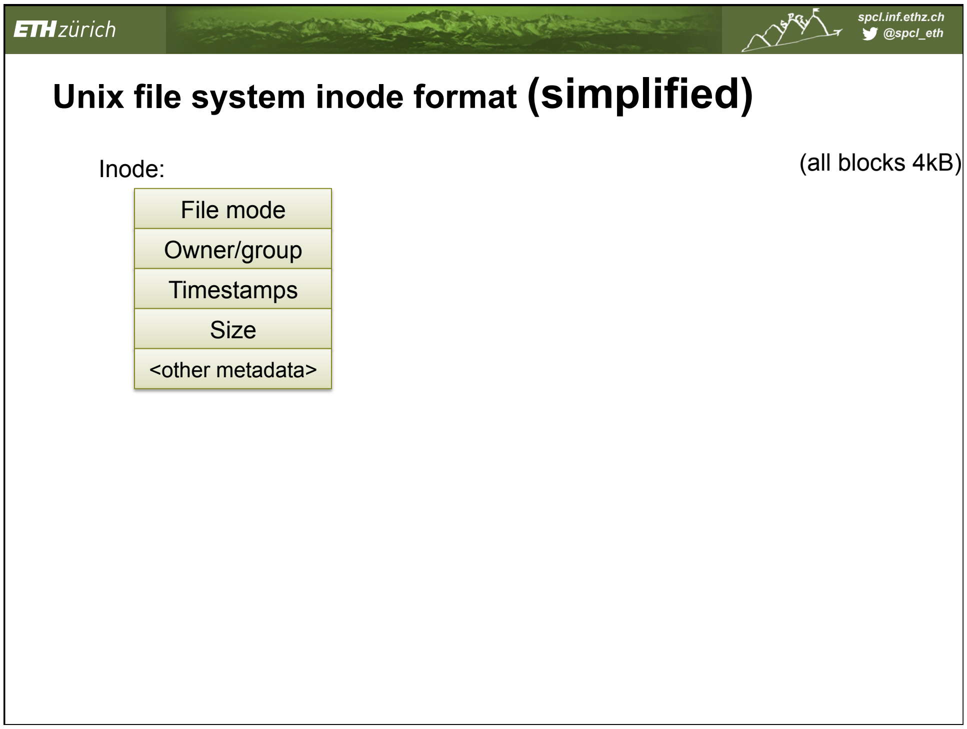


File is represented by an *index block* or ***inode***

- File metadata
- List of blocks for each part of file
- Directory contains pointers to inodes

Inode and file size in FFS

- **Example:**
  - Inode is 1 block = 4096 bytes
  - Block addresses = 8 bytes
  - Inode metadata = 512 bytes
- **Hence:**
  - (4096-512) / 8 = 448 block pointers
  - 448 * 4096 = 1792kB max. file size



ETH zürich

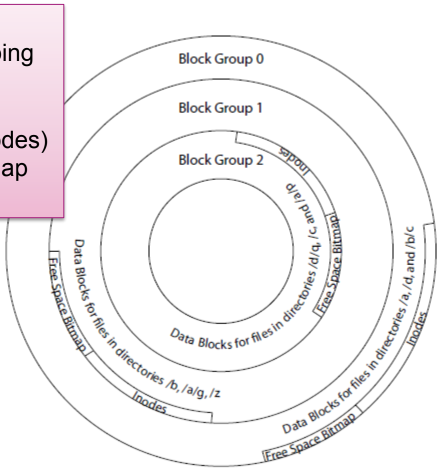
Very large files: tree keeps random access efficient

Free space map

- **FFS uses a simple bitmap**
  - Initialized when the file system is created
  - One bit per disk (file system) block
- **Allocation is reasonably fast**
  - Scan though lots of bits at a time
  - Bitmap can be cached in memory

Block groups

1. Optimize disk performance by keeping together related:
   - Files
   - Metadata (inodes)
   - Free space map
   - Directories



Block Group 0
Block Group 1
Block Group 2
Inodes
/d/q, /c, and /a/p

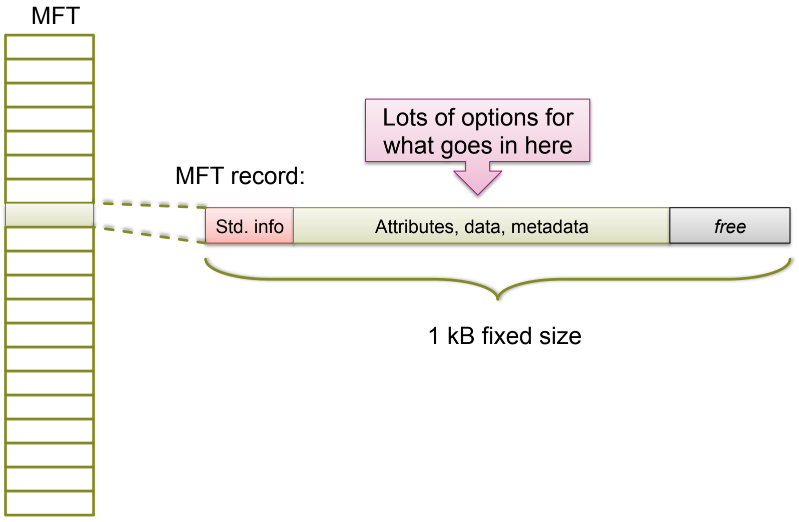
NTFS

NFTS Master file table



MFT

Lots of options for what goes in here

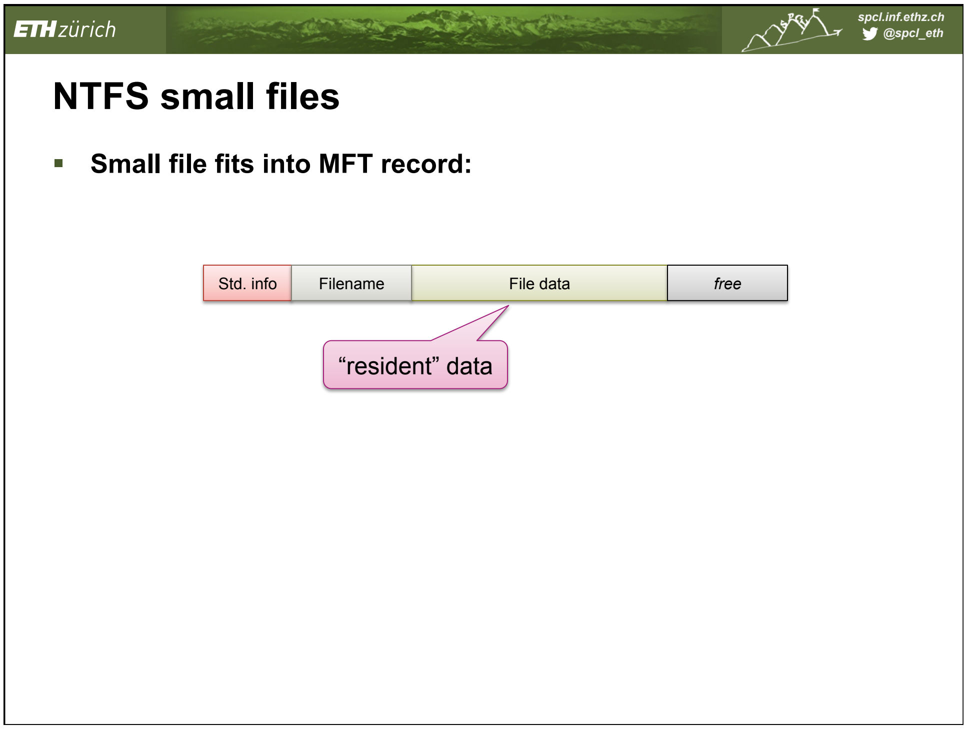
MFT record:

Std. info

Attributes, data, metadata

free

1 kB fixed size

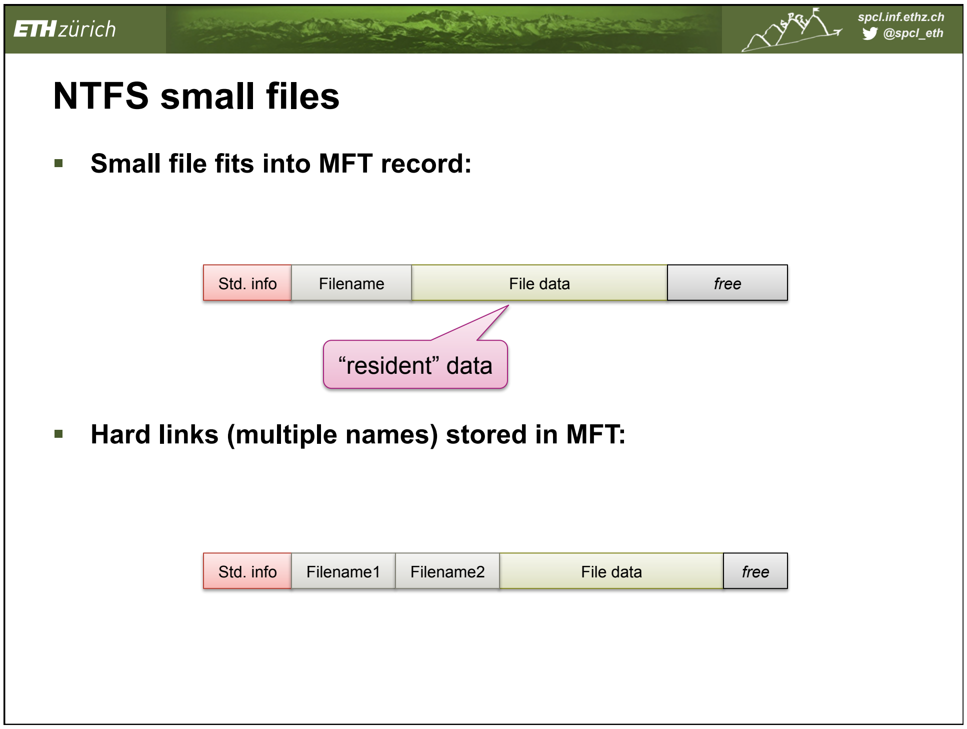


NTFS small files

- **Small file fits into MFT record:**

Std. info	Filename	File data	*free*

"resident" data



NTFS small files

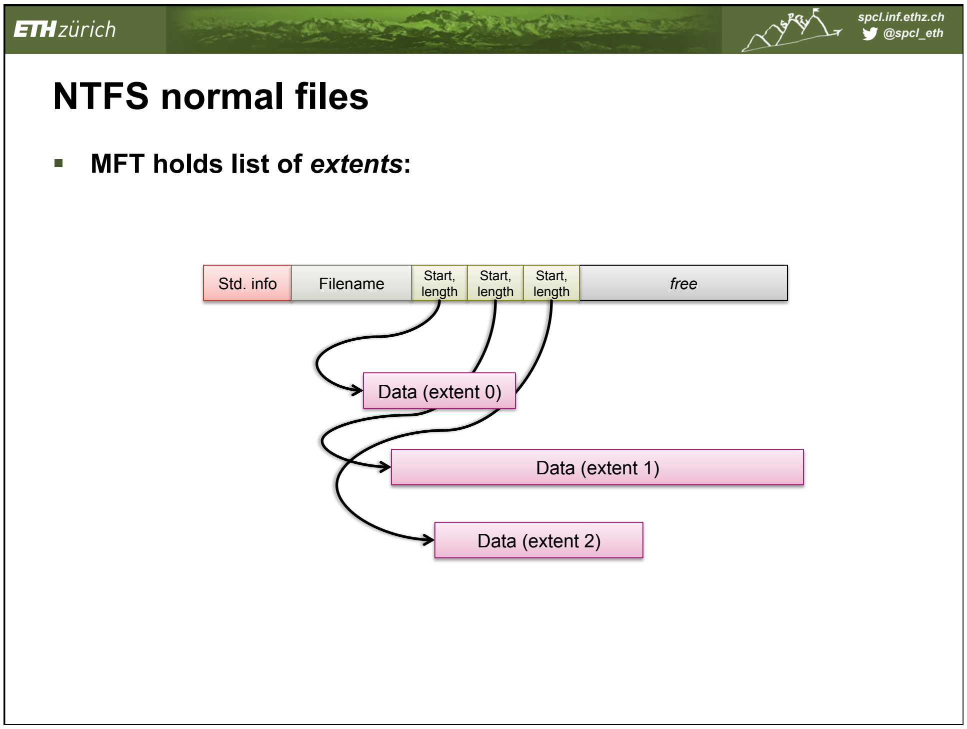
- **Small file fits into MFT record:**

Std. info	Filename	File data	*free*

"resident" data

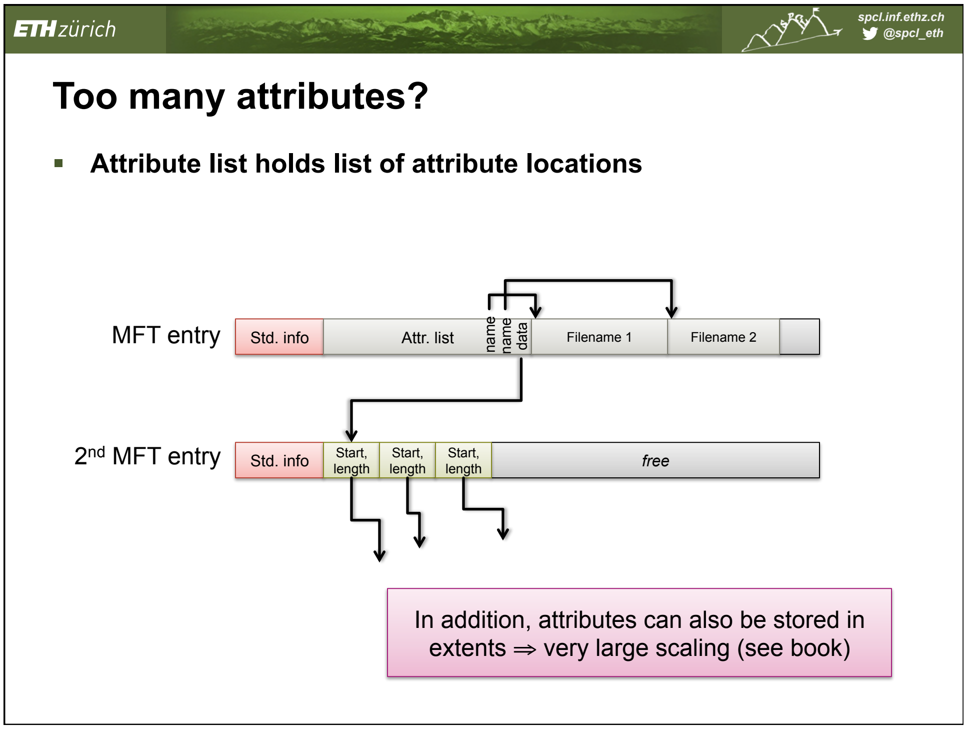
- **Hard links (multiple names) stored in MFT:**

Std. info	Filename1	Filename2	File data	*free*



NTFS normal files

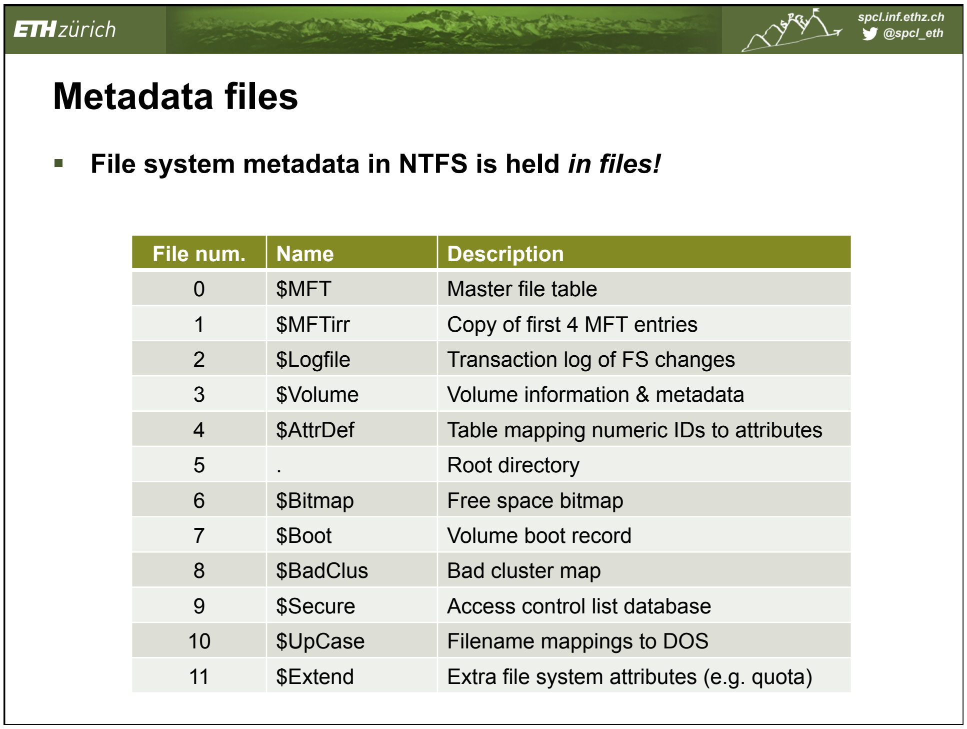
- **MFT holds list of *extents*:**



Too many attributes?

- **Attribute list holds list of attribute locations**

In addition, attributes can also be stored in extents ⇒ very large scaling (see book)



ETH zürich

Metadata files

- **File system metadata in NTFS is held *in files!***

File num.	Name	Description
0	$MFT	Master file table
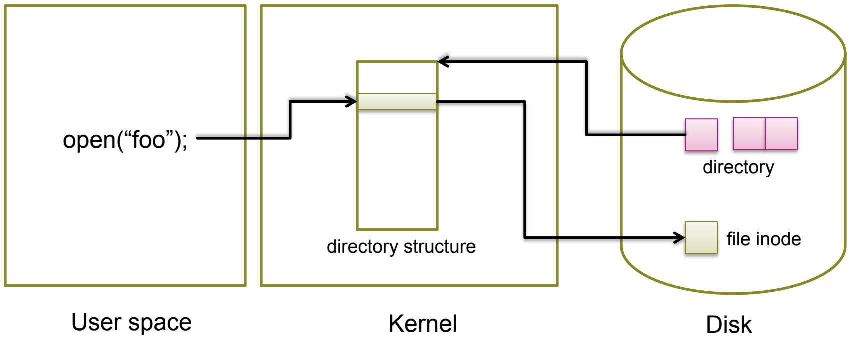
1	$MFTirr	Copy of first 4 MFT en
2	$Logfile	Transaction log of FS cha
3	$Volume	Volume information & metad
4	$AttrDef	Table mapping numeric IDs t
5	.	Root directory
6	$Bitmap	Free space bitmap
7	$Boot	Volume boot record
8	$BadClus	Bad cluster map
9	$Secure	Access control list database
10	$UpCase	Filename mappings to DOS
11	$Extend	Extra file system attributes (e.g. quota)

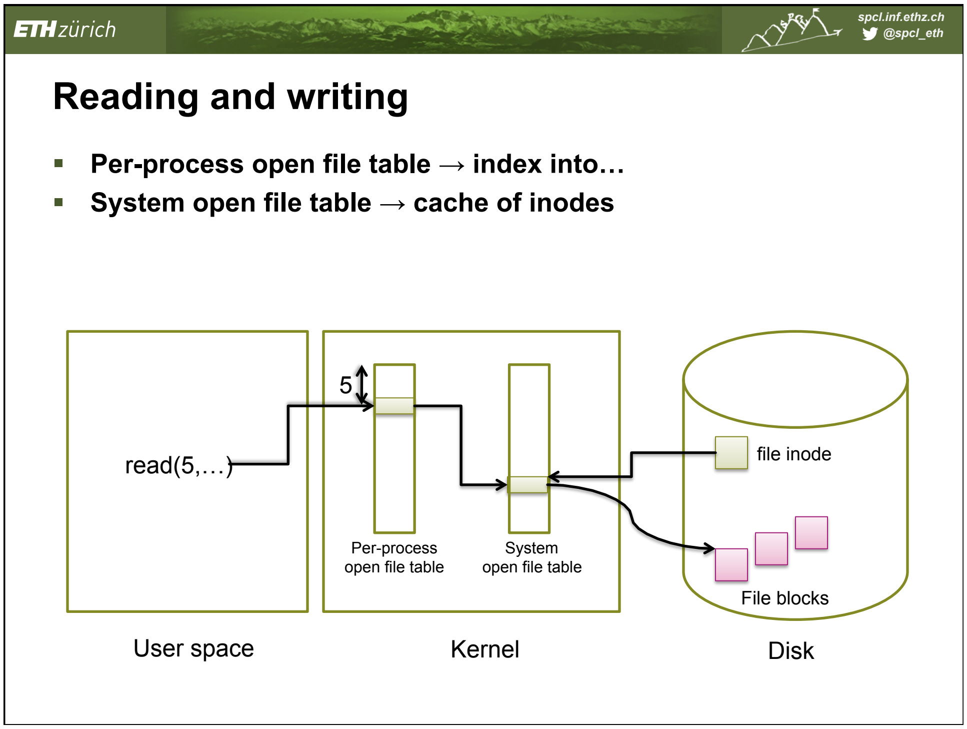
Question:
Huh?
Where is it then?
Answer:
First sector of volume points to first block of MFT

In-memory data structures

Opening a file

- **Directories translated into kernel data structures on demand:**





Reading and writing

- **Per-process open file table → index into…**
- **System open file table → cache of inodes**

read(5,…)

5

Per-process open file table

System open file table

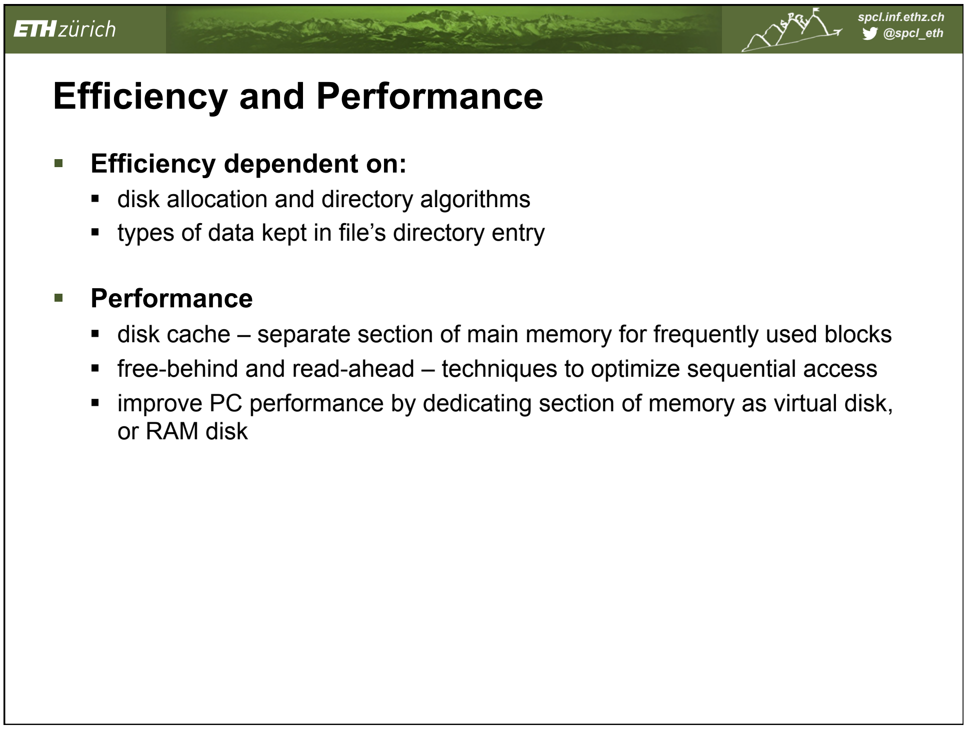
file inode

File blocks

User space

Kernel

Disk



Efficiency and Performance

- **Efficiency dependent on:**
  - disk allocation and directory algorithms
  - types of data kept in file's directory entry
- **Performance**
  - disk cache – separate section of main memory for frequently used blocks
  - free-behind and read-ahead – techniques to optimize sequential access
  - improve PC performance by dedicating section of memory as virtual disk, or RAM disk

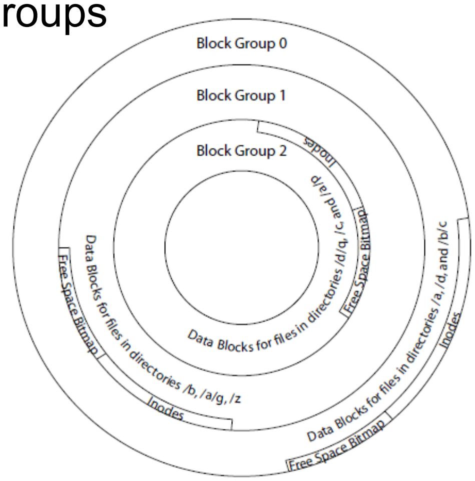
Addendum

1. **FAT file size limit (4 GB) – due to the file length entry in the FAT table (guess what, 32 bits)**
   - Volume size is up to 16 TB (2^{32} * 4k blocks)

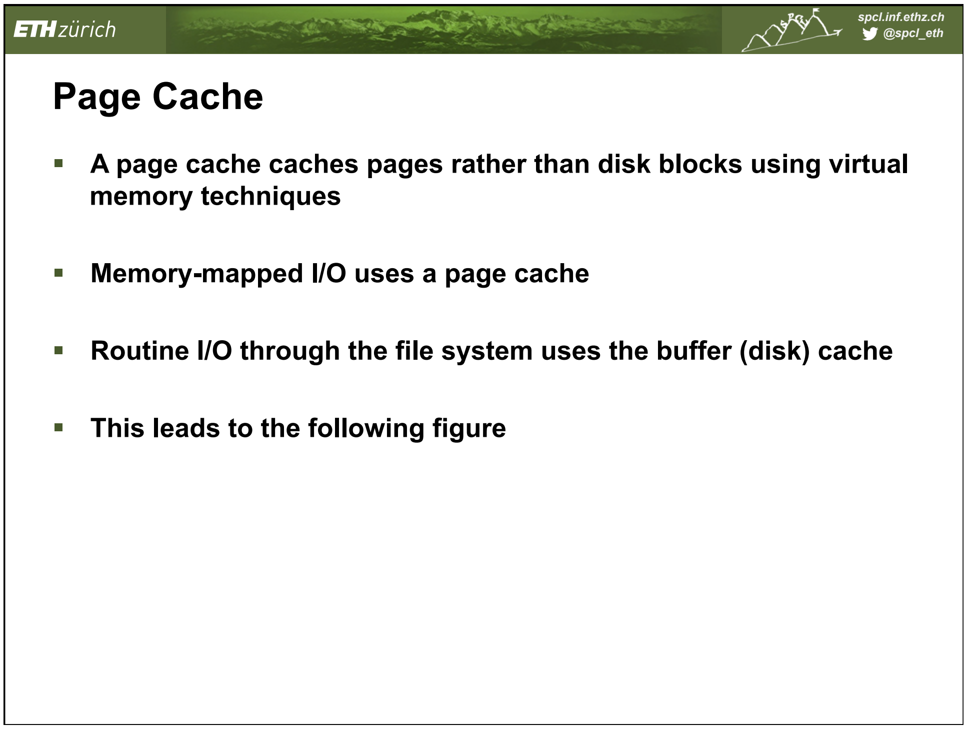
3. **Insert data into the middle of a file**
   - May allocate a block (true)
   - But who wants to insert only block sizes?
   - Solution: Streams (D'oh, not in FFS/ext…?)

Addendum

3. Block Groups

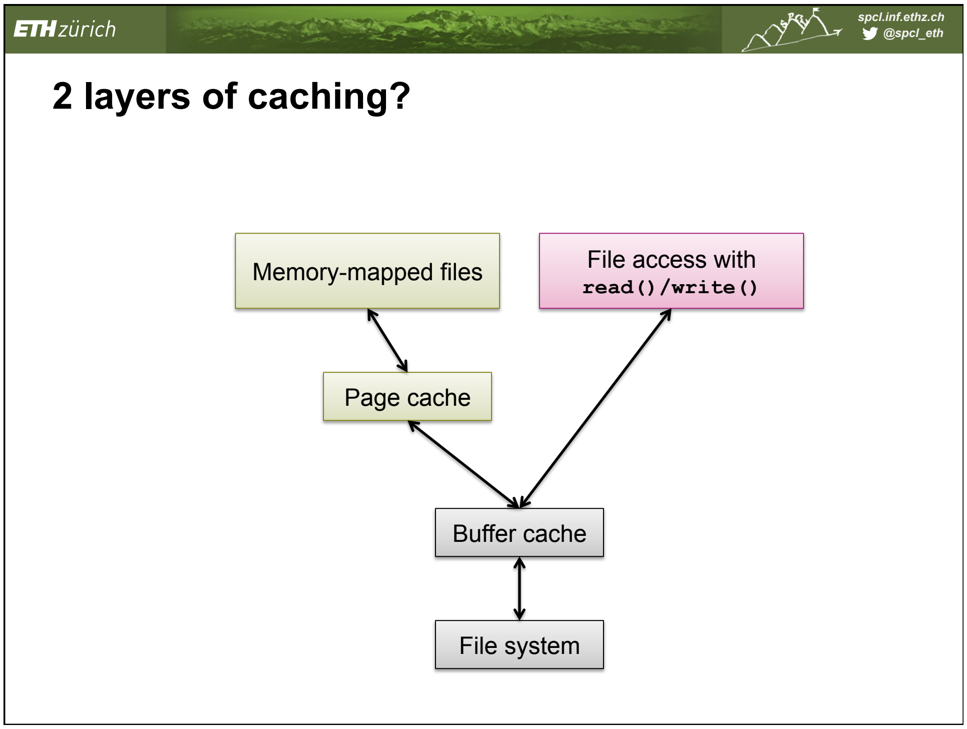


Block Group 0
Block Group 1
Block Group 2
Inodes
Data Blocks for files in directories /d/q, /c, and /a/p
Free Space Bitmap
Data Blocks for files in directories /b, /a/g, /z
Free Space Bitmap
Inodes
Data Blocks for files in directories /a, /d, and /b/c
Free Space Bitmap
Inodes

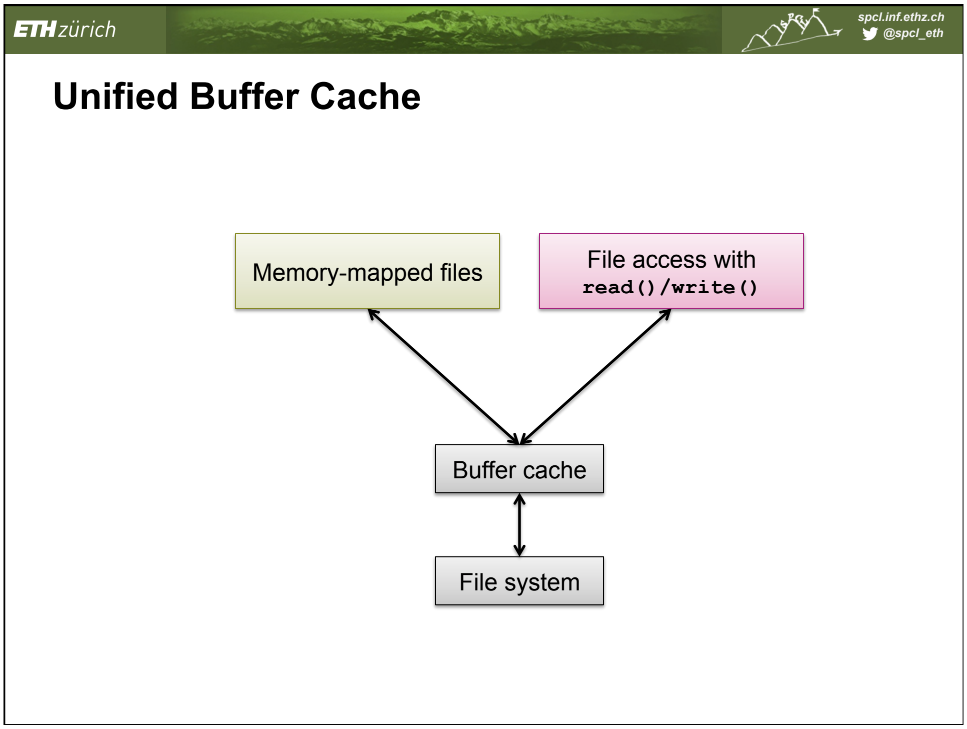


Page Cache

- A page cache caches pages rather than disk blocks using virtual memory techniques
- Memory-mapped I/O uses a page cache
- Routine I/O through the file system uses the buffer (disk) cache
- This leads to the following figure



2 layers of caching?



Unified Buffer Cache

Memory-mapped files

File access with `read()/write()`

Buffer cache

File system

Recovery

- **Consistency checking – compares data in directory structure with data blocks on disk, and tries to fix inconsistencies**
- **Use system programs to back up data from disk to another storage device (floppy disk, magnetic tape, other magnetic disk, optical)**
- **Recover lost file or disk by restoring data from backup**
